San Antonio, Texas

BULLETIN 1

CHEMICAL ANALYSES OF WATER FROM OBSERVATION WELLS IN THE EDWARDS AND ASSOCIATED LIMESTONES, SAN ANTONIO AREA, TEXAS

Compiled by
Sergio Garza, Hydraulic Engineer
United States Geological Survey

Prepared in cooperation with the Geological Survey,
United States Department of the Interior,
the Texas Water Commission, and
the City of San Antonio

December 1962

CHEMICAL ANALYSES OF WATER FROM OBSERVATION WELLS
IN THE EDWARDS AND ASSOCIATED LIMESTONES, SAN ANTONIO AREA, TEXAS

Compiled by
Sergio Garza, Hydraulic Engineer
United States Geological Survey

December 1962

The city of San Antonio and other water users in the San Antonio area have been concerned about the possibility of the encroachment of saline water into the fresh water-bearing part of the aquifer supplying the area. As a result, a program was begun in 1959 to resample wells tapping the zone of transition between water of good quality and saline water in the Edwards and associated limestones, in order to detect changes in quality of the water as the head in the aquifer changed. This program is part of a more extensive hydrologic investigation being carried on by the U.S. Geological Survey in cooperation with the Edwards Underground Water District, the Texas Water Commission, and the city of San Antonio. As part of this program, about 120 wells are resampled twice a year; the water is analyzed in the laboratory of the Geological Survey in Austin, Tex., for specific conductance, pH, chloride, sulfate, bicarbonate, and hardness. A more complete chemical analysis is made for one of the samples from each well in the program. These more complete analyses are on file in the offices of the Geological Survey in Austin and San Antonio.

Chemical analyses of water from 129 wells are shown in the table in this report. The analyses of samples collected before 1959 for many of the wells are shown also. Some of the wells are no longer in use, but chemical analyses of previous samples from these wells are carried in the records, although future sampling may not be possible. Figure 1 shows the location of the resampled wells and an arbitrary boundary line between water of good quality, containing less than 1,000 parts per million (ppm), and saline water, containing more than 1,000 ppm of dissolved solids (Garza, 1962, p. 38).

The U. S. Public Health Service (1962, p. 2152-2155) has established standards for maximum concentrations of certain constituents in drinking water. These standards are commonly used in evaluating water for use as a public supply. The standards should not be exceeded when other more suitable supplies are available. The standards for some of the constituents given in table 1 are as follows: Chloride (Cl) should not exceed 250 ppm. Sulfate (SO_4) should not exceed 250 ppm. Dissolved solids should not exceed 500 ppm.
