## **EDWARDS AQUIFER HYDROGEOLOGIC REPORT FOR 1998**

Compiled by:

Roberto Esquilin, Hydrogeologist

**December 1999**

## **CONTENTS**

ACKNOWLEDGEMENTS .....	v
1.0 INTRODUCTION .....	1
2.0 WATER LEVELS .....	3
3.0 PRECIPITATION.....	7
3.1 Precipitation in the Edwards Aquifer Region.....	7
3.2 Precipitation Enhancement Program.....	11
4.0 GROUNDWATER RECHARGE.....	12
5.0 GROUNDWATER DISCHARGE & USAGE.....	18
6.0 WATER QUALITY.....	25
6.1 Water Quality in the Edwards Aquifer .....	25
Primary and Secondary Drinking Water Standards .....	28
6.2 Freshwater/Saline-water Interface Study.....	29
6.3 Surface Water Quality Data .....	30
7.0 SUMMARY .....	31
8.0 DEFINITIONS.....	32
9.0 REFERENCES .....	35

## **TABLES**

2.1 Annual water level highs and lows for selected index wells in the San Antonio Region of the Edwards Aquifer, 1934-1998 .....	4
3.1 Annual water precipitation for selected rain gauges in the Edwards Aquifer Region, 1934-1998.....	9
3.2 Monthly precipitation data from Edwards Aquifer Authority rain gauge network and National Oceanic and Atmospheric Administration precipitation gauging stations, 1998 .....	10
4.1 Drainage basins that cross the Edwards Aquifer Recharge Zone .....	12
4.2 Estimated annual groundwater recharge to the Edwards Aquifer by drainage basin, 1934-1998.....	14
4.3 Monthly groundwater recharge at Parker Creek recharge structure, 1998.....	15

4.4	Estimated annual Edwards Aquifer recharge from Edwards Aquifer Authority recharge projects.....	17
5.1	Annual estimated groundwater discharge data by county for the Edwards Aquifer, 1934-1998.....	20
5.2	Estimated spring discharge from the Edwards Aquifer, 1998.....	21
5.3	Total groundwater discharge from the Edwards Aquifer, 1998 .....	22
5.4	Annual estimated Edwards Aquifer groundwater discharge by use, 1955-1998 .....	23
6.1	Groundwater quality standards.....	26
6.2	Secondary drinking water standards.....	28
6.3	Classification of groundwater quality based on total dissolved solids.....	29

## **FIGURES**

1.1	Edwards Aquifer and other physiographic features in the San Antonio Region.....	2
2.1	Water level comparison between the monthly average of record (1934-1998) and the monthly highs for 1998 at the Bexar County index well, AY-68-37-203 .....	6
3.1	Sites in the Real Time Data Network used by the Edwards Aquifer Authority to monitor precipitation .....	7
3.2	Annual and average precipitation for San Antonio, 1934-1998.....	8
4.1	Major drainage basins and Edwards Aquifer Authority recharge structures in the San Antonio Region of the Edwards Aquifer .....	13
4.2	Estimated annual recharge and ten-year floating average recharge for the San Antonio area of the Edwards Aquifer (1934-1998).....	16
5.1	Major springs in the San Antonio Region of the Edwards Aquifer .....	19
5.2	Groundwater pumping compared to springflow in the Edwards Aquifer 1934-1998.....	22

## **APPENDICES**

<b>APPENDIX A – WATER LEVEL DATA.....</b>	<b>37</b>
A-1 City of Kyle well (LR-67-01-809) daily high water levels (in feet above MSL), 1998 .....	38
A-2 Landa Park well (DX-68-23-302) daily high water levels (in feet above MSL), 1998 .....	38
A-3 City of Castroville well (TD-68-41-301) daily high water levels (in feet above MSL), 1998 .....	39
A-4 City of Hondo index well (TD-69-47-306) daily high water levels (in feet above MSL), 1998 .....	39
A-5 J-17, Bexar County index well (AY-68-37-203) daily high water levels (in feet above MSL), 1998 .....	40
A-6 City of Uvalde index well (YP-69-50-302) daily high water levels (in feet above MSL), 1998 .....	40
<b>APPENDIX B – WATER QUALITY DATA.....</b>	<b>41</b>

## **PLATES** (Located in pocket at back of report)

- 2.1 Water level observation network
  - 3.1 Real Time Data collection network
    - 6.1 Water quality – wells, springs and streams sampled

## **ACKNOWLEDGMENTS**

The Authority staff extends our appreciation to municipalities, agencies (federal, state, and local), and other well owners who participated in this study by granting access to their wells, land, and records. Particular thanks are extended to the members of the south central Texas study unit of the United States Geological Survey - National Water Quality Assessment (USGS-NAWQA) for their efforts in the collection and analysis of some of the data presented in this report. Also, Authority staff extends our gratitude to the United States Geological Survey - Water Resources Division (San Antonio Subdistrict) for their work in compiling and calculating the recharge to and discharge from the Edwards Aquifer.

## **1.0 INTRODUCTION**

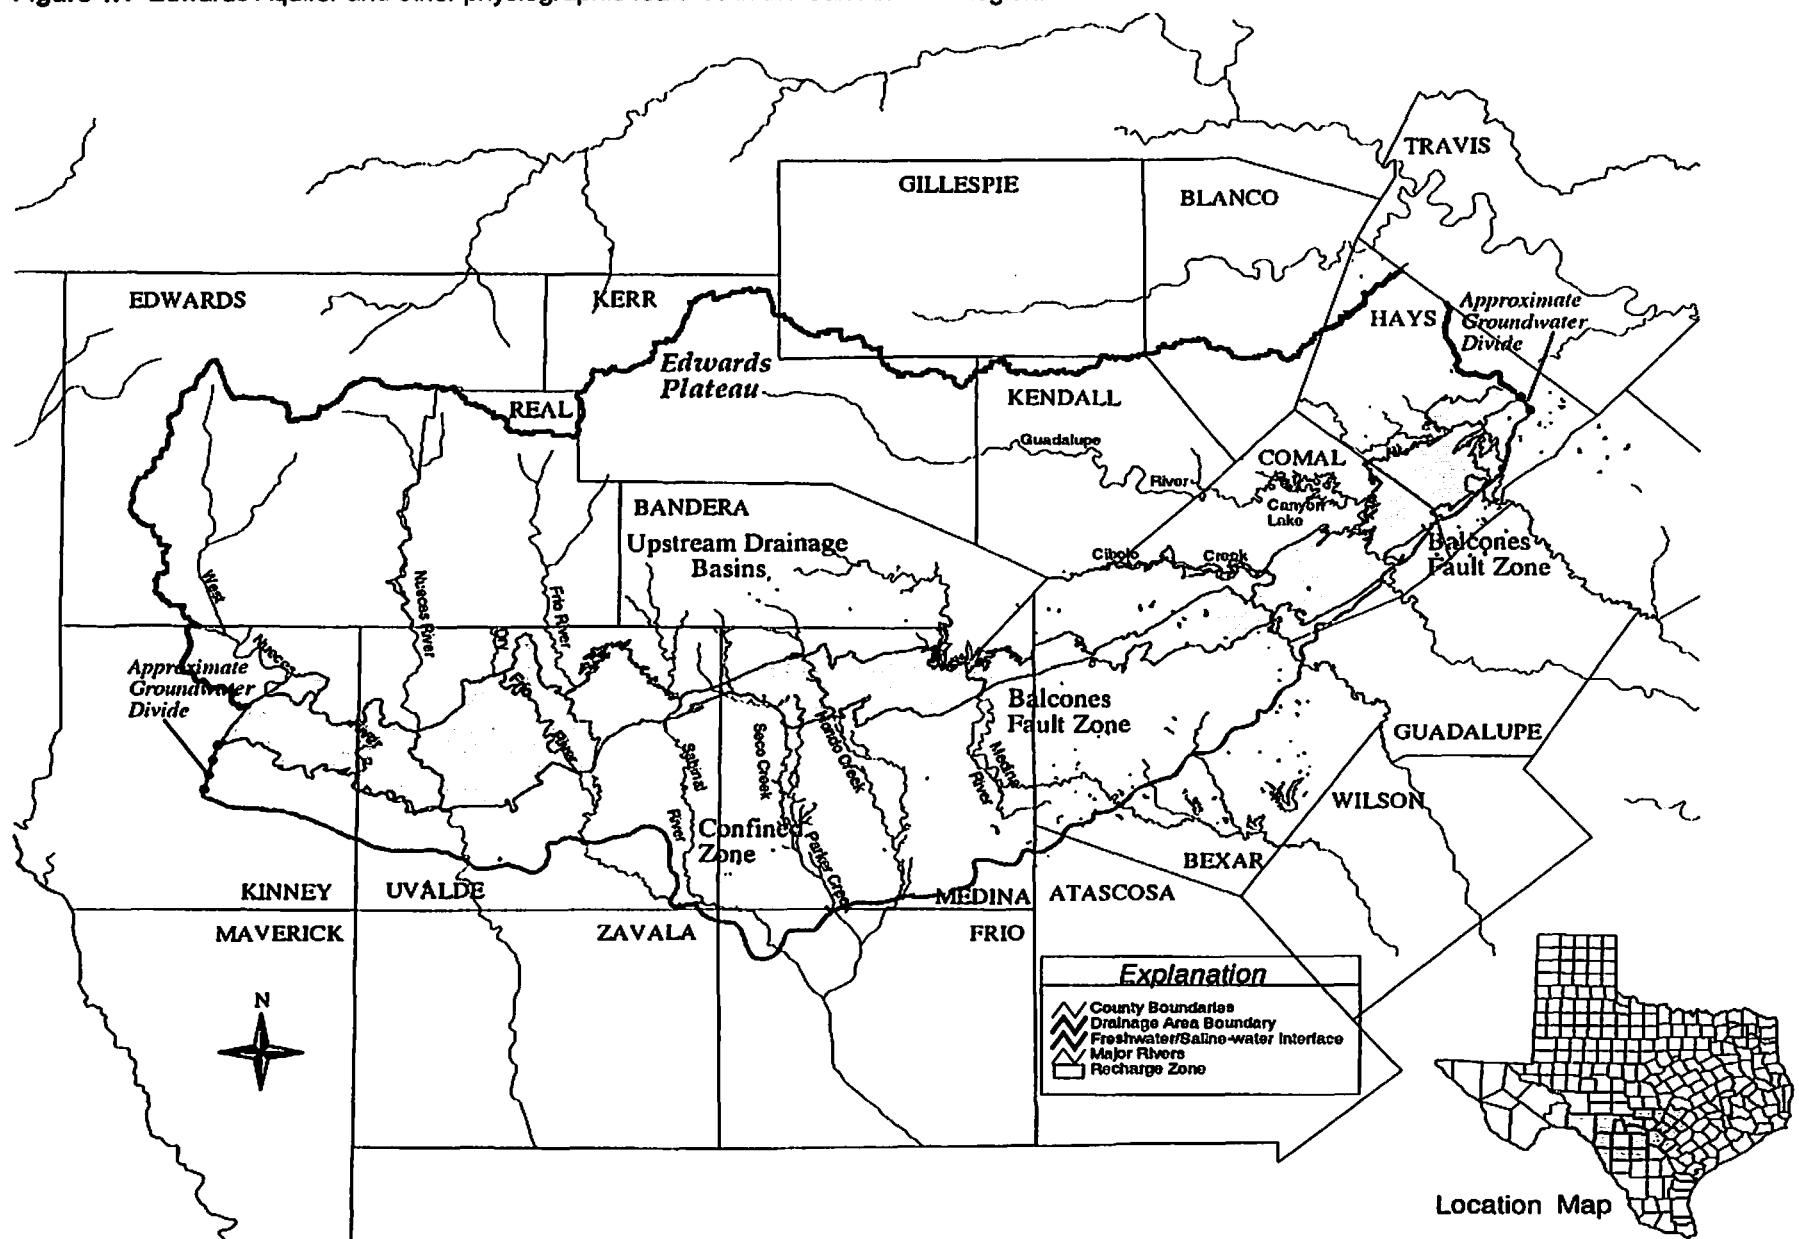

The Edwards Aquifer is one of the most permeable and productive limestone aquifers in the United States. In the San Antonio region, the aquifer extends from the groundwater divide near Brackettville in Kinney County to the groundwater divide near Kyle in Hays County (Figure 1.1). The aquifer provides potable water to approximately one and one half million people in the region.

The Edwards Aquifer Authority (the Authority) encompasses all or parts of an eight-county area of south central Texas, including Uvalde, Medina, Bexar, Atascosa, Comal, Hays, Guadalupe, and Caldwell counties. The Authority was created by the Texas Legislature in 1993 to replace the Edwards Underground Water District (EUWD) and to manage, preserve and protect the Edwards Aquifer. The Authority is governed by a 17-member board of directors, with voting members elected to represent the 15 districts across the region, and two non-voting members appointed by other entities. Directors represent agricultural, industrial, municipal, spring and downstream user groups. The Legislature also created a South Central Texas Water Advisory Committee to interact with the Authority when issues related to downstream water rights are addressed.

The Legislature mandated the Authority take all necessary measures to effectively control the resource to protect domestic and municipal water supplies, the operation of existing agriculture and industries, terrestrial and aquatic life, and the economic development of the region. To accomplish these goals, the Authority is vested with all of the powers, rights and privileges necessary to manage, conserve, preserve and protect the Edwards Aquifer, and to increase the recharge of, and prevent the waste or pollution of water in, the aquifer.

This report addresses the San Antonio Region of the Edwards Aquifer. It presents quantitative and qualitative data collected in 1998, as well as an historical perspective by providing annual data for the period of record (1934-1998). Information concerning water levels and water quality are provided in this report.

Figure 1.1 Edwards Aquifer and other physiographic features in the San Antonio Region.

## 2.0 WATER LEVELS

Periodic water level measurements from a variety of wells have been compiled since 1929 in the San Antonio region of the Edwards Aquifer. These periodic measurements were enhanced with the introduction of continuous water level recorders in some of the observation wells in the 1930s by the United States Geological Survey (USGS). The Authority has further enhanced its ability to collect the data with the introduction of continuous digital recorders, developing a groundwater network from eastern Kinney County to central Hays County. Plate 2.1 shows the locations of the Authority's observation well network within the Edwards Aquifer region. The water level observation network consists of wells equipped with water level recorders located in both the water table (unconfined) and the artesian (confined) zones of the Edwards Aquifer. All water level measurements are made in feet above mean sea level (MSL).

More than 850,000 water level measurements from 25 digital recorder-equipped observation wells, as well as monthly measurements from 17 periodic observation wells were recorded in 1998 as part of the Authority's water level data collection program. The digital recorders measure water levels across the aquifer every 15 minutes, 365 days a year. These wells are equipped with a float device or a pressure transducer for water level readings. Data is recorded on digital storage cards and then downloaded during a monthly site inspection, or by modem to the Authority's office. To augment the water level observation network, Authority staff measures water levels at 17 observation wells on a monthly basis during normal aquifer conditions, and at least 50 additional wells during periods of extreme high or low water level conditions. These periodic measurements are made manually with steel tape and electric line measuring devices. Water level data collected by the Authority is also forwarded to federal, state and regional agencies.

The Authority, and its predecessor the EUWD, have also collected water level data from the Trinity Aquifer (Glen Rose Formation) in northern Bexar County since 1991, and alluvial aquifers of the Leona Formation in southern Uvalde County since 1966. The Edwards and Trinity aquifers are hydraulically connected, allowing pathways for groundwater flow to and from the Edwards Aquifer. The Leona Formation in the vicinity of the Leona River in southern Uvalde County is recharged by the Edwards Aquifer. Water level monitoring of the Edwards Aquifer and associated hydrogeologic units adds to the base of scientific knowledge, and helps in the management of this regional water resource.

Historical water level trends in observation wells, along with corresponding precipitation and discharge information, are necessary to determine the volume of groundwater in the aquifer during any given period. Water level increases generally indicate greater quantities of water are recharging the aquifer than are being discharged. During periods when groundwater recharge is greater than discharge, springflow increases in proportion to increases in groundwater levels. Likewise, during drought or high-demand conditions, water levels and springflows generally decline, reflecting greater groundwater discharge than groundwater recharge. Table 2.1 shows the annual records of high and low water levels measured in five selected Edwards Aquifer observation wells.

In 1998, total recharge was generally greater than total discharge as demonstrated by the increased water levels from January to March, and August to December. There was a decrease in the water levels between April and July (Appendix A: Tables A-1 – A-6). The net increase in water levels at the Bexar County index well [J-17 (AY-68-37-203)] between January and March was 10.0 feet (671.5 feet above MSL in January to 681.5 feet above MSL in March). The net increase in water levels at the J-17 well between August and November was 48.9 feet above MSL (640.0 ft above MSL in August to 688.9 ft above MSL in November).

**Table 2.1 Highest and lowest recorded water levels for selected index wells in the San Antonio Region of the Edwards Aquifer, 1934-1998 (measured in feet above Mean Sea Level).**

Data source: USGS, and Edwards Aquifer Authority, 1999.

"a" Continuous monitoring equipment established on October 24, 1940.

"b" Continuous monitoring equipment established on May 25, 1950.

"c" Continuous monitoring equipment established on January 1, 1963.

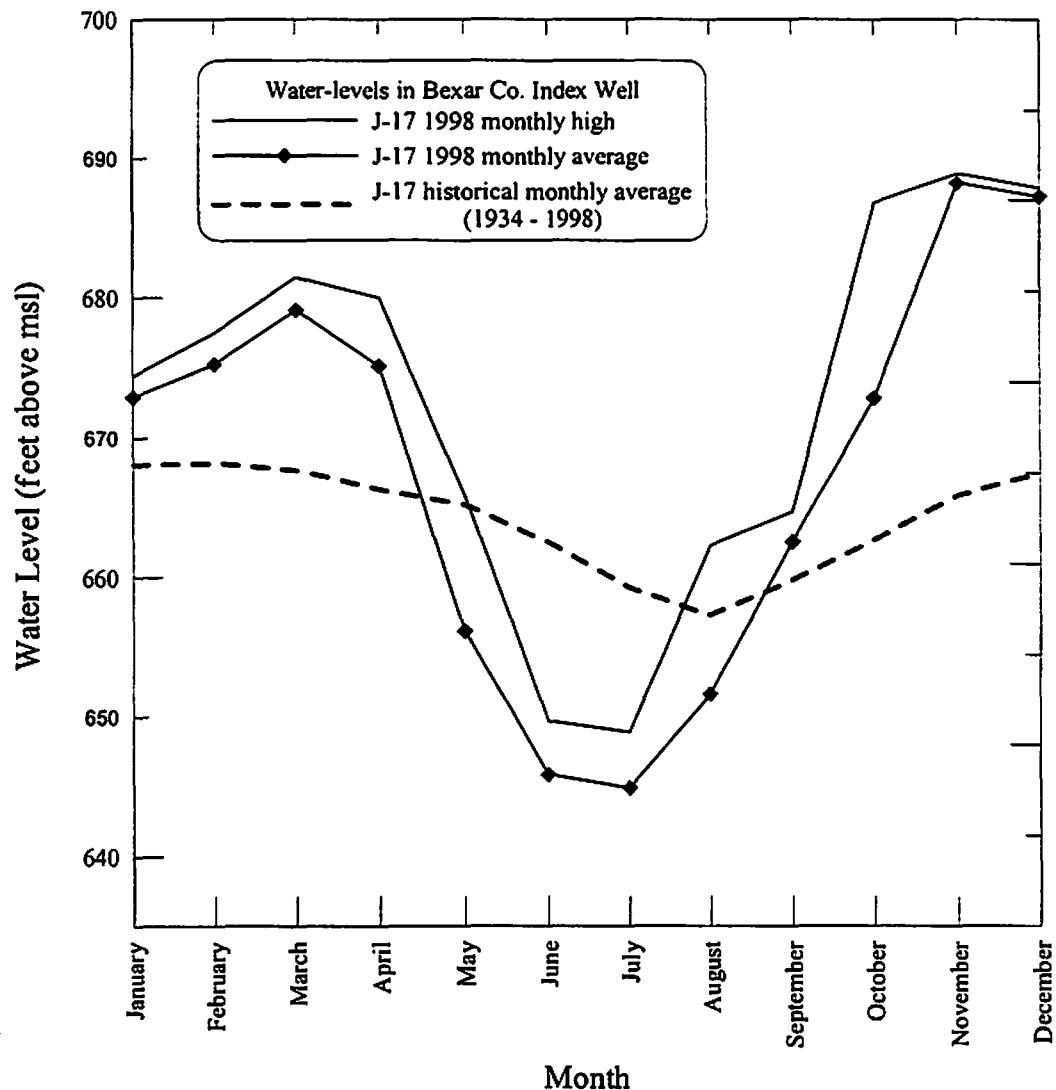

"d" Continuous monitoring equipment established on November 4, 1948.

"e" Values based on monthly tape down measurements (No continuous monitoring equipment installed in this well).

In October 1998, a weather system brought over 12 inches of rainfall to southeastern Texas. San Antonio received 18.07 inches of rain between October 17 and 18 (NOAA, 1998), and the water levels in the Bexar County index well [J-17 (AY-68-37-203)] rose 6.72 feet within a 24-hour period. The water level measured at J-17 was 686.3 feet above MSL by the end of the year (Figure 2.1).

Overall, the water levels in the Edwards Aquifer increased slightly during 1998 relative to the levels recorded in 1997 (Table 2.1). The average annual water level for 1998 (667.7 feet above MSL) at J-17 was higher than the average historic level of 664.2 feet above MSL. The Edwards Aquifer water levels were below the trigger level at J-17 for Stage I of the Authority's Critical Period Management Plan (i.e., at or below 650 feet MSL) from June 1, 1998 until July 26, 1998. The water levels were below the J-17 trigger level for Stage II of the Critical Period Management Plan (i.e., at or below 642 feet MSL) during the last week of July and the first week of August 1998, then returned to Stage I levels until the last week of August. The Critical Period Management Plan was implemented in February 1997 when the groundwater levels fluctuated between 650 ft and 648.8 ft above MSL. The Critical Period Management Plan became effective in April 1998 (Rick Illgner, personal communication, 1998). Figure 2.1 compares the average water level for the period of record and maximum water levels for the year 1998. Tables A-1 through A-6 in Appendix A show 1998 water levels for selected observation wells.

**Figure 2.1** Water level comparison between the monthly average of record (1934-1998), the monthly highs for 1998, and the monthly average at the Bexar County index well, AY-68-37-203 (J-17)

## 3.0 PRECIPITATION

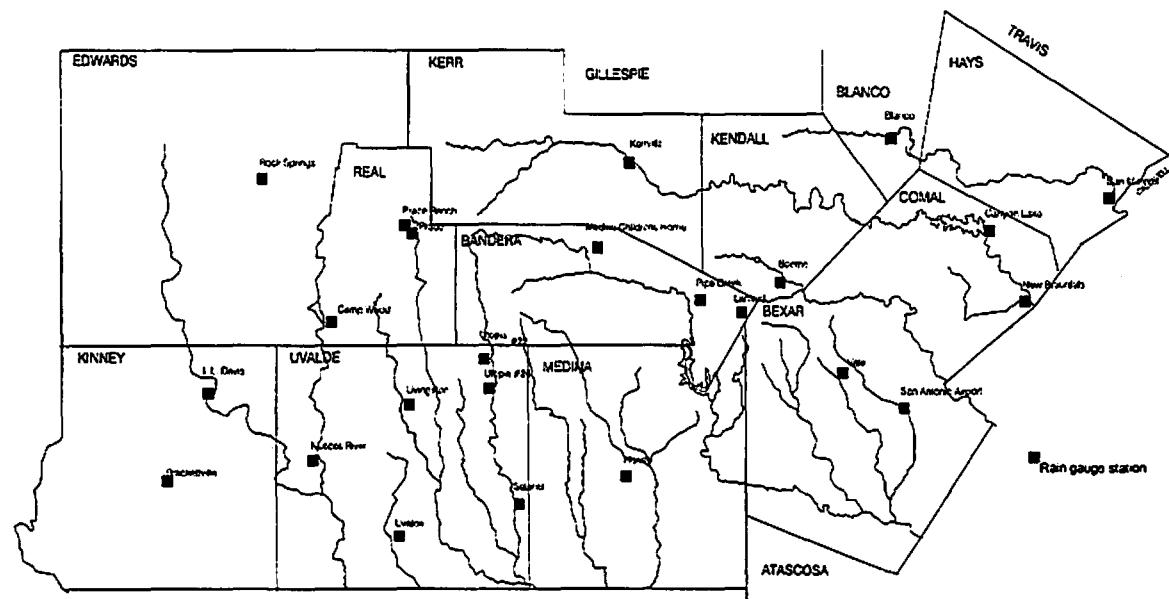

### 3.1 Precipitation in the Edwards Aquifer Region

Precipitation is the primary source of recharge to the Edwards Aquifer. Water levels monitored by the Authority's network of observation wells across the Artesian Zone rise within hours of a heavy rainfall event on the Edwards Aquifer Recharge Zone (EARZ) or associated upstream drainage basins in the central Texas Hill Country.

Annual precipitation in the Edwards Aquifer region is monitored by the Authority to determine the volume of groundwater recharge to the aquifer. Precipitation data is gathered from Authority rain gauge stations, National Oceanic and Atmospheric Administration (NOAA) weather stations, and the USGS rain gauge stations located across the EARZ and upstream drainage basins. Figure 3.1 is a map showing the locations of the precipitation gauging stations the Authority uses to record area rainfall.

A Real Time Data Network, consisting of 68 rain gauge observation sites, reports precipitation data at six-minute intervals to the Authority's office. In addition, daily precipitation data is forwarded every month to the Authority from seven rain gauge observation sites located on the EARZ. This information is augmented with data from numerous weather and rain gauge stations maintained by NOAA and the USGS. The precipitation information is used to calculate recharge and to monitor any precipitation trends that may affect recharge to the Edwards Aquifer. Plate 3.1 indicates the locations of all Real Time Data Network sites.

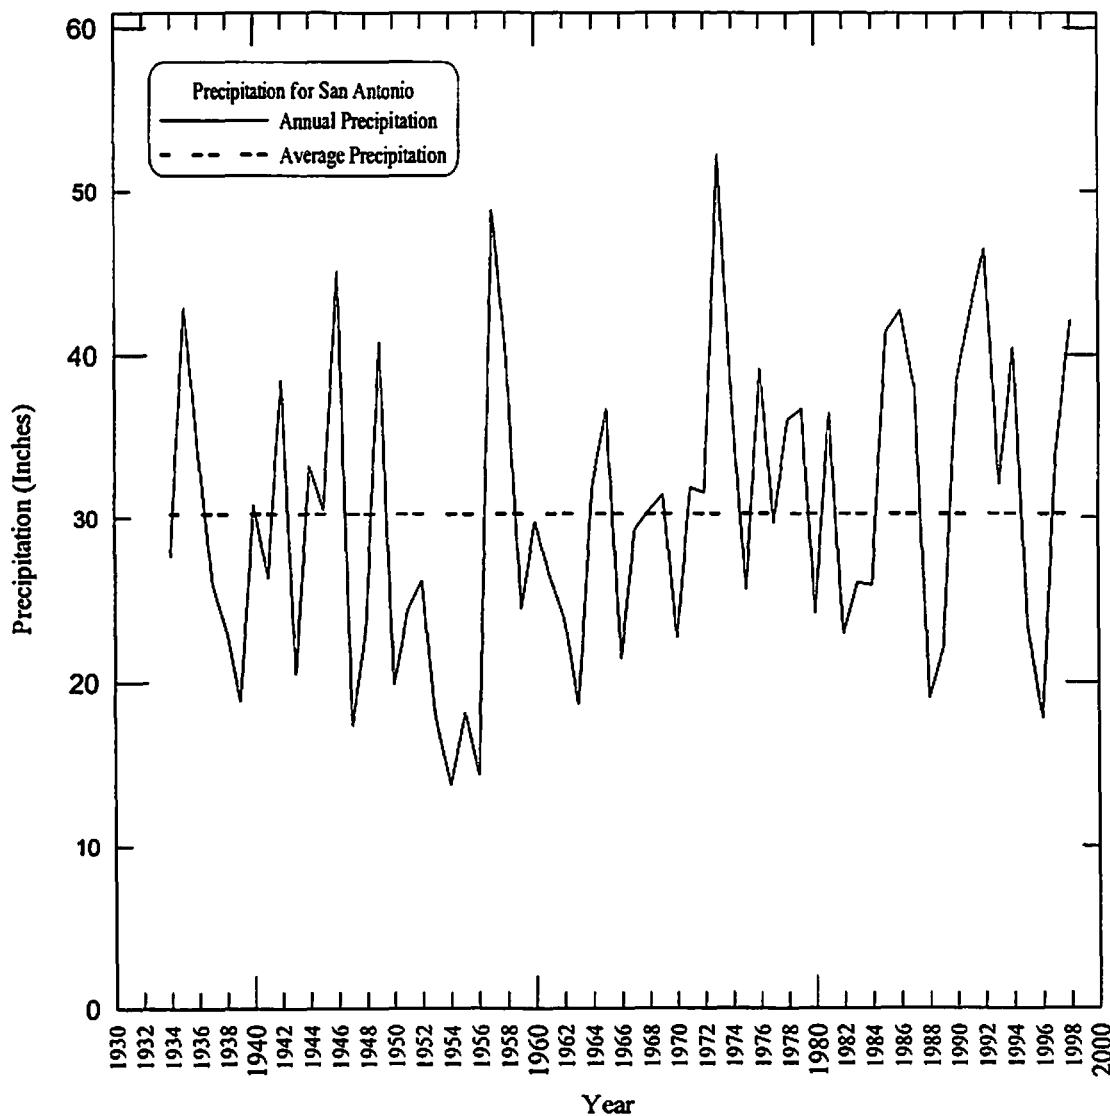

**Figure 3.1** Sites in the Real Time Data Network used by the Edwards Aquifer Authority to monitor precipitation.

Precipitation data for San Antonio has been maintained since 1871 by national weather service agencies. Historical aquifer water levels, recharge and springflow are closely related to precipitation and decrease during periods of low precipitation.

The amount of rainfall received in the San Antonio region in 1998 was approximately 39% above normal. Average precipitation in San Antonio for the period between 1934 and 1998 is 30.23 inches. In 1998, total precipitation measured at the San Antonio International Airport was 42.10 inches. However, 14.42 inches fell within a two-day period in October 1998 in the San Antonio area (NOAA, 1999). When comparing the Edwards Aquifer water levels from the low levels observed in 1997, recovery in 1998 can be directly attributed to increased precipitation within the Edwards Aquifer recharge and catchment zones. Figure 3.2 demonstrates a hydrograph of precipitation for San Antonio from 1934 to 1998. Table 3.1 shows annual precipitation for selected rain gauges in the region. Table 3.2 shows monthly measurements for 1998 at selected rain gauge stations across the region.

Figure 3.2 Annual precipitation and average precipitation for San Antonio, 1934-1998.

**Table 3.1 Annual precipitation for selected rain gauges in the Edwards Aquifer Region, 1934-1998  
(measured in inches).**

Data source: Edwards Aquifer Authority and US Department of Commerce (NOAA), 1999.

-- indicates missing or incomplete data for the month.

The San Antonio region is situated between a semi-arid area to the west and a wetter more humid area to the east. This location allows for large variations in monthly and annual precipitation amounts. The average annual precipitation for San Antonio is approximately 30 inches, however annual precipitation has ranged from 10 inches to near 50 inches (NOAA, 1999). Weather systems moving across the area in October 1998 provided a large percentage of the regions 1998 rainfall. In October 1998, San Antonio received 8 days of rainfall, totaling 18.07 inches -- nearly twice the record high amount of rainfall previously recorded for October (9.74 inches in 1994). October 17, 1998, set a single day record rainfall event for San Antonio at 11.26 inches (NOAA, 1999). Over the past 30 years for the month of October, the San Antonio region of the Edwards Aquifer has averaged about 7 days of rain, totaling 2.62 inches.

The Edwards Aquifer Authority's automated rain gauge system recorded from 2.5 inches of rain in Uvalde County to 24 inches of rain in Comal County during the weekend of October 17. The greatest intensity of the rainfall was distributed through central and northwest Comal County. The National Weather Service reported up to 24 inches of rain from October 17 through 19 near New Braunfels. Individual weather observers reported up to 27 inches northwest of New

Braunfels during the same time period, with the greatest amount falling on October 17 (NOAA, 1999).

The record rainfall event in the San Antonio region during the weekend of October 17, 1998 resulted in a record rate of increase in the Edwards Aquifer water level, as measured at J-17, of 6.72 feet over a 24-hour period. Likewise, the October 1998 water level in the Hondo monitor well also rose markedly in synchronization with the record rainfall event, while the water level in the Uvalde monitor well rose approximately one foot (Appendix A).

### **3.2 Precipitation Enhancement Program (PEP)**

The Edwards Aquifer Authority Board of Directors voted in the Fall of 1997 to obtain a permit from the Texas Natural Resources Conservation Commission (TNRCC) to conduct precipitation enhancement (cloud-seeding). The permit was granted by the TNRCC in October 1998 and is valid for four years beginning in January 1999 and ending in December 2002. The permit allows the Authority to conduct precipitation enhancement anytime during the year, including the traditional period of April through September.

Research indicates that precipitation enhancement can result in increased rainfall of approximately 10 to 15 percent. The Authority believes this increase in rainfall could add 10 percent of additional recharge to the Edwards Aquifer. Additional benefits may be realized if the rain does not fall over the aquifer's Recharge Zone since increased rainfall also decreases pumpage demand for lawn watering and crop irrigation.

## **4.0 GROUNDWATER RECHARGE**

The segment of the Edwards Aquifer Recharge Zone (EARZ) that supplies groundwater to the San Antonio region of the Edwards Aquifer extends from central Kinney County to central Hays County. **Figure 4.1** identifies the major drainage basins that cross the EARZ. These basins are also listed below in **Table 4.1**.

**Table 4.1** Drainage basins that cross the Edwards Aquifer Recharge Zone.

**Nueces-West Nueces River basin**  
**Frio-Dry Frio River basin**  
**Sabinal River basin**  
**Area between Sabinal River and Medina River basins**  
**Medina River basin**  
**Area between Medina River and Cibolo-Dry Comal Creek basins**  
**Cibolo Creek and Dry Comal Creek basin**  
**Guadalupe River basin**  
**Blanco River basin**

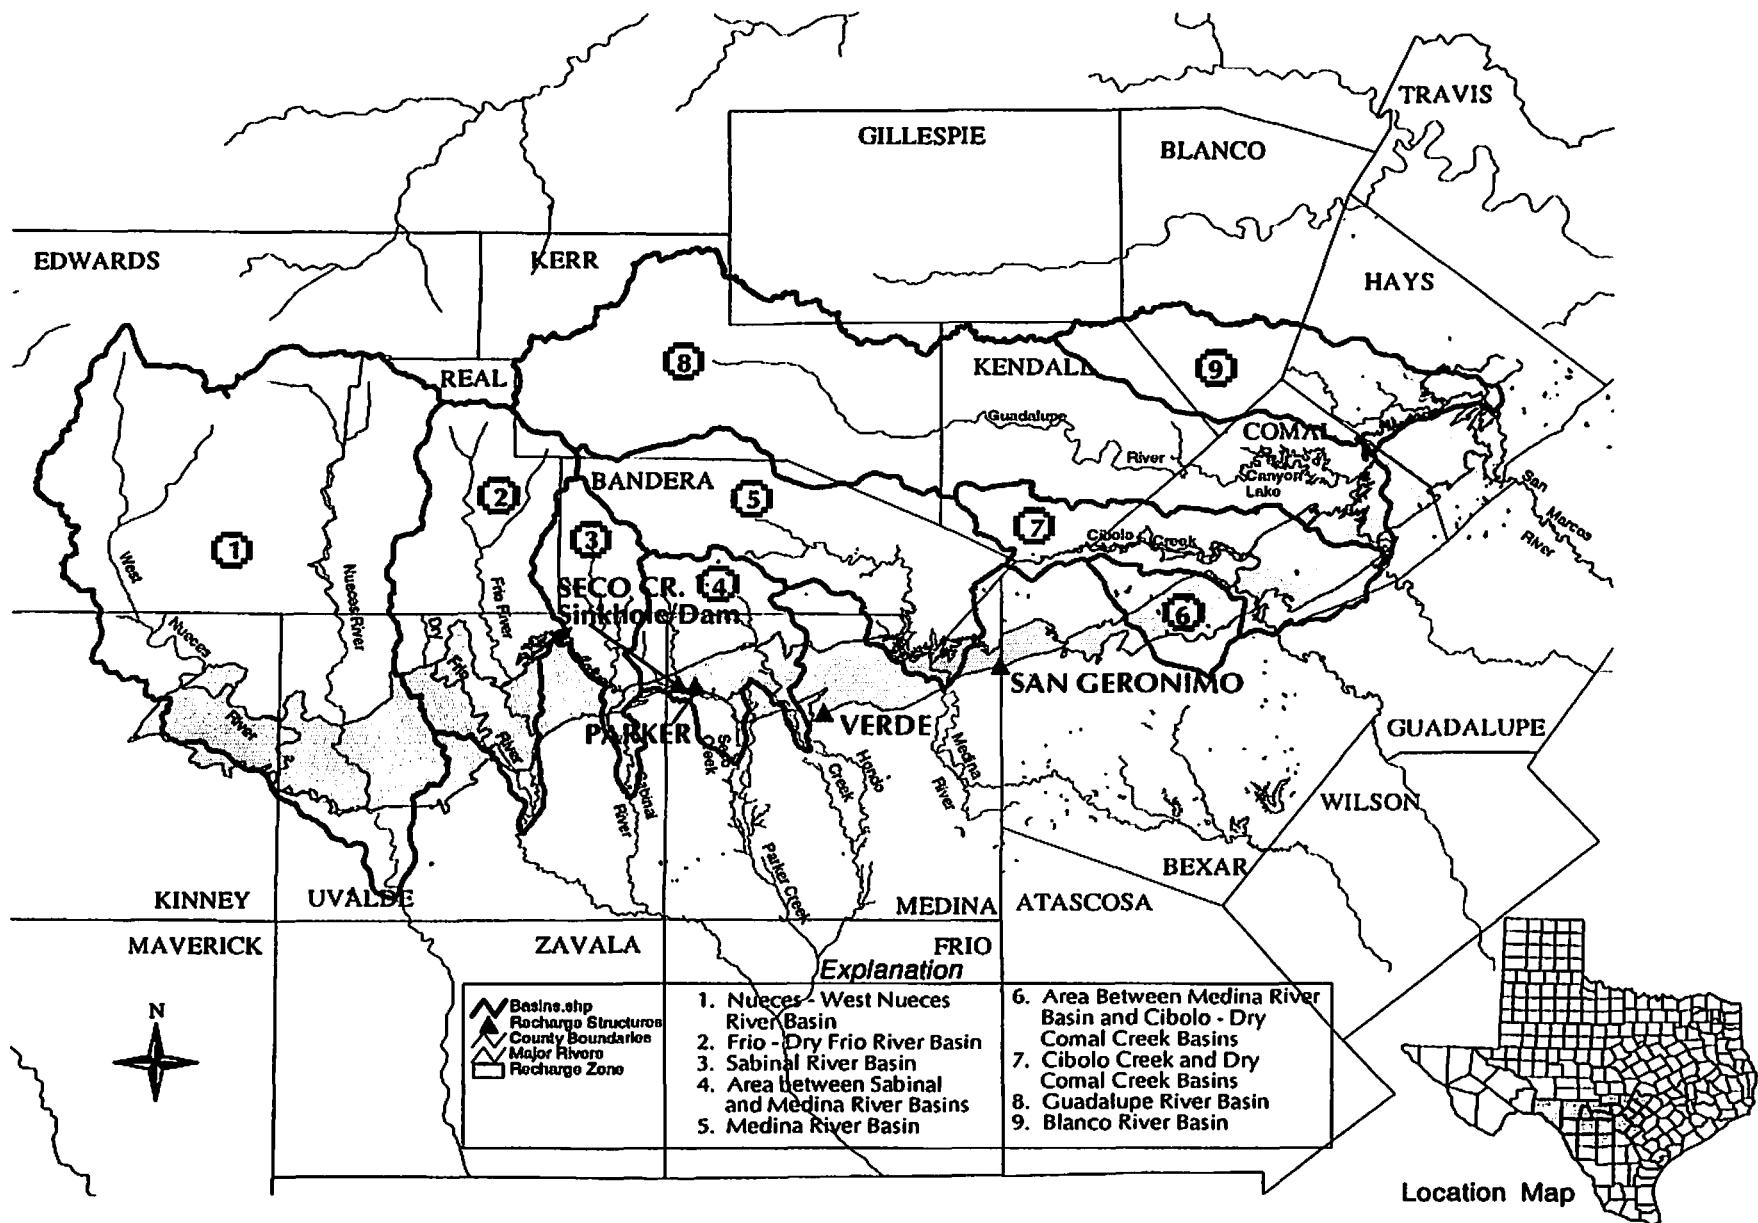

Although some recharge to the Edwards Aquifer is provided by other hydraulically connected aquifers, this type of recharge has not been quantified. Only surface water data from precipitation and streamflows are utilized to calculate total recharge.

The USGS has been calculating groundwater recharge to the Edwards Aquifer since 1934. **Table 4.2** shows estimated annual recharge by river basin from 1934 through 1998, based on USGS calculations. The USGS estimates that annual recharge for the period of record (1934 to 1998) ranges from 43,700 acre-feet at the height of the drought of record in 1956, to 2,486,000 acre-feet in 1992. In 1998, estimated recharge was 1,142,300 acre-feet. Average annual recharge from 1934 to 1998 was 683,100 acre-feet. However, since 1989, the ten-year average annual recharge has been estimated to be approximately 945,000 acre-feet. **Figure 4.2** depicts a graph of yearly recharge and the ten-year floating average recharge estimate for the San Antonio region of the Edwards Aquifer from 1934 to 1998.

Recharge directly affects groundwater levels in the aquifer. Water levels rise during years of higher-than-normal recharge, and generally decline during periods of below-normal recharge. Since recharge is a direct result of precipitation, water levels in the aquifer are greatly affected by rainfall. Higher than normal rainfall conditions in 1998 resulted in a slight increase of recharge to the Edwards Aquifer relative to the 1997 recharge estimate.

The Authority operates four recharge dams across the EARZ. The locations of the recharge structures are shown in **Figure 4.1**. In, 1998, gauges were operational at only one of these recharge structures, Parker Creek Dam. **Table 4.3** shows the 1998 monthly recharge to the Edwards Aquifer from the Parker Creek recharge structure. The USGS collected recharge data, and estimated the recharge amount for Parker Creek Dam through September 1998. The available 1998 Parker Creek Dam recharge data are provisional. **Table 4.4** shows the annual historical recharge recorded, or estimated for each site since construction.

Figure 4.1 Major drainage basins and Edwards Aquifer Authority recharge structures in the San Antonio Region of the Edwards Aquifer.

**Table 4.2** Estimated annual groundwater recharge to the Edwards Aquifer by drainage basin, 1934-1998 (measured in thousands of acre-feet).

"a" Provisional data.

"b" Determined by linear regression analysis.

"---" indicates no data available.

The 1998 recharge calculations shown in Table 4.4 for Verde Creek, San Geronimo, and Seco Creek dams were determined by a linear regression analysis, using the "least squares" method. The "linear regression" method was also implemented for the remaining three months of Parker Creek Dam (Table 4.3). For each area, a comparison of rainfall data in the relevant drainage basin (obtained from the National Weather Service) to historical recharge data for the dam was used as data input. The resulting data were used to generate a linear regression equation. This equation was used to predict the amount of recharge at each of the four recharge structures for a given rainfall within the basin. A comparison of the resulting data to historical recharge indicates the regression results are reasonable (Gregory James, written communication, 1998).

The historical average annual recharge attributed to the recharge dams is based on a period of record that reflects the date of construction through 1998. The historical average annual recharge contributed by the combined structures is 3,268 acre-feet.

## 5.0 GROUNDWATER DISCHARGE AND USAGE

The Edwards Aquifer provides water for many diverse uses in South Central Texas, including irrigation, municipal, industrial, and domestic/recreational needs. Groundwater is discharged from the Edwards Aquifer as springflow or through wells.

Springflow supports recreational economies in New Braunfels and San Marcos, and provides habitat for threatened and endangered animal and plant species. The amount of groundwater discharged as springflow is greater than the amount discharged through wells for any of the above-mentioned uses. Springflow is calculated by measuring the downstream flow from springs, or by measuring water levels in observation wells near the springs, and then making the necessary corrections from these values. **Figure 5.1** is the location map of the major springs of the Edwards Aquifer. The groundwater discharge resulting from pumping is calculated by tabulating reported water use data from public supply, irrigation, agricultural, industrial, commercial and domestic wells.

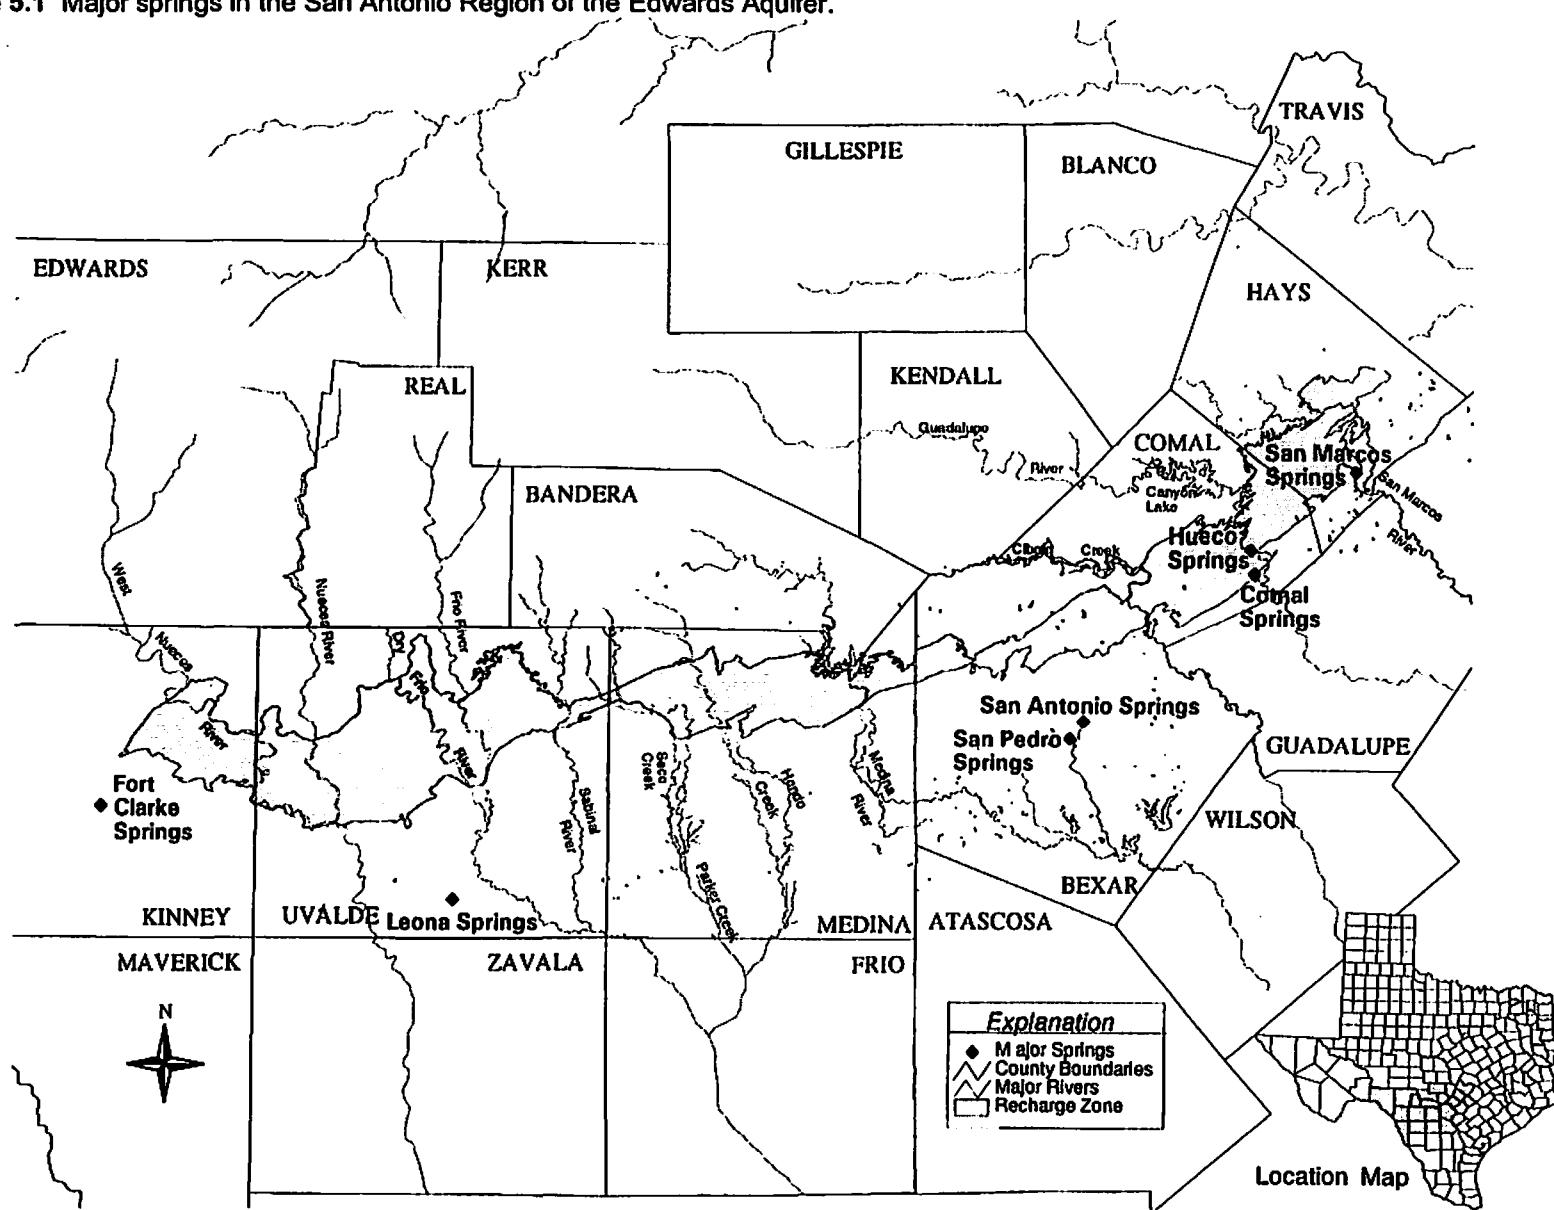

Estimates of annual groundwater discharge from springflow and pumping for the San Antonio area of the Edwards Aquifer are available from 1934 to 1998 (**Table 5.1**). Annual groundwater discharges range from the calculated low of 388,800 acre-feet in 1955 to the calculated high of 1,130,000 acre-feet in 1992. In 1998, total groundwater discharge from the Edwards Aquifer from wells and springs was estimated at 917,600 acre-feet.

Springflow from 1934 to 1998 has varied from a low of 69,800 acre-feet in 1956 to a high of 802,800 acre-feet in 1992 (**Table 5.1**). **Table 5.2** shows the monthly estimated discharge in 1998 for six primary Edwards Aquifer springs. Spring discharge from the Edwards Aquifer for 1998 was calculated at 464,100 acre-feet. Spring discharge accounted for 51 percent of total discharge from the Edwards Aquifer in 1998 (**Tables 5.1 and 5.2**).

While springflow can vary greatly from year to year and is dependent on precipitation and aquifer water levels, groundwater pumping has progressively increased over the years. **Figure 5.2** is a graph comparing Edwards Aquifer groundwater withdrawal to springflow. The lowest estimated annual aquifer pumping level was 101,900 acre-feet recorded in 1934. Since 1934, pumping from the Edwards Aquifer has increased to 453,500 acre-feet, or an increase of approximately 300 percent. Average annual well production was estimated to be 298,500 acre-feet per year for the period of record from 1934 to 1998, while the estimated floating 10-year average for pumping from 1989 through 1998 was 435,100 acre-feet (**Table 5.1**). Reported groundwater pumping accounted for 453,500 acre-feet of water discharged from the Edwards Aquifer in 1998.

**Table 5.3** shows the 1998 discharge data by use for the counties in the region. The discharge estimates were compiled from pumpage data reported by public water supply, industry, military, and irrigators to the Authority, TWDB, and USGS. Pumpage from domestic supply, stock, and miscellaneous use were estimated by the USGS (USGS, 1999), and the Authority. **Table 5.4** shows annual estimated Edwards Aquifer groundwater discharge by use from 1955 to 1999.

**Figure 5.1** Major springs in the San Antonio Region of the Edwards Aquifer.

**Table 5.1 Annual estimated groundwater discharge data by county for the Edwards Aquifer, 1934-1998 (measured in thousands of acre-feet).**

"b" includes estimates from Guadalupe County discharge by Edwards Aquifer users.

Differences may occur due to rounding procedures.

\*In 1995 the USGS revised the method of calculating domestic/livestock pumpage, which significantly decreased the estimate for 1995 and 1996.

The Authority and the USGS estimated discharge from the Edwards Aquifer in 1998. In previous years, the USGS determined the total amount of irrigated acreage from county tax rolls, which have remained relatively constant over recent years. County soil and water conservation districts provided estimates of irrigation "duties" for selected crop types. The USGS multiplied these duties by amounts of irrigated acreage by crop type as provided by the U.S. Department of Agriculture (USDA), thereby determining an estimate of irrigation uses from the Edwards Aquifer. The USDA no longer provides this data making this method of estimation impossible to use.

The Authority initiated the Edwards Aquifer Well Metering Program in 1997. This program requires that all municipal, industrial, and irrigation Edwards Aquifer wells be metered. The Authority utilized well pumpage data from the Well Metering Program to estimate well discharge. Use of direct pumpage data has significantly improved the discharge estimating process.

## **6.0 GROUNDWATER QUALITY**

### **6.1 Water Quality in the Edwards Aquifer**

The Authority, in cooperation with the USGS and TWDB, has conducted a systematic program of water quality data collection since 1968. Through this cooperative effort, the Authority has maintained a network of groundwater and surface water sites for gathering water quality data across the entire area of the Edwards Aquifer. Analyses of these data have been used by the Authority to monitor changes in aquifer water quality. The Authority's Water Quality Protection Program is to ensure long-term protection of groundwater quality in the Edwards Aquifer and the streams crossing over the Edwards Aquifer Recharge Zone.

In 1998, the Authority in cooperation with the USGS and San Antonio Water System (SAWS) collected water quality samples from 63 wells, 4 springs, and 8 streams. The locations of these sites are shown in **Plate 6.1**. These samples were analyzed in the field for selected water quality parameters and in the laboratory for inorganic and organic chemical constituents. The field analysis included temperature, pH, conductivity, and alkalinity. The laboratory analyses included common major ions, minor elements (metals, including heavy metals), Total Dissolved Solids (TDS), nutrients, pesticides, herbicides, volatile organic compounds and other selected analytes. The parameters analyzed and their typical concentrations in groundwater are listed in **Table 6.1**.

In 1998, 63 wells in the Edwards Aquifer were sampled and analyzed for the occurrence of minor element metals. Laboratory analyses indicated that several wells, such as the saline zone transect wells, in San Antonio, New Braunfels, and San Marcos, and private wells in Medina County and in Uvalde County, contained some minor element metal concentrations above the method detection limit (MDL). The analytical values in the subject wells were extremely low with all but one well containing no more than 20 percent of the maximum contaminant level (MCL). The one exception, well TD-68-42-806, indicated a lead concentration above the MCL. In general, these analytical values correspond to typical aquifer results for minor element metal content, as seen in **Table 6.1**.

In 1998, water samples were collected for Volatile Organic Compounds (VOC) analysis at 8 stream and 4 spring locations distributed across the aquifer region. The samples indicated no detectable levels of any of the VOC's analyzed. The 8 stream and 4 spring locations were also sampled and analyzed for pesticides and herbicides. The samples indicated no detectable levels of any of the pesticides and herbicides compounds analyzed.

The Authority participated with the USGS in the National Water Quality Assessment (NAWQA) Program to establish a 30-well monitoring network on the EARZ. The objective of the study is to correlate the quality of recently recharged groundwater with different types of urban land use. Drilling of the 30 wells was completed in the summer of 1998, and water quality samples were collected by the USGS in the last quarter of 1998. The NAWQA study results will be presented by the USGS at a later date. The results of this study will assist the Authority in developing strategies for monitoring land development activities over the EARZ.

**Table 6.1** Groundwater quality standards.

Parameter	Current Maximum or Secondary Contaminant Levels	Edwards Aquifer Typical Range of Results

Data source: EPA maximum contaminant levels, 40 CFR , Part 141, 1995.

"a" Risk-based maximum contaminant level listed in 30 TAC Chapter 335, Subchapter S dated 10-24-99.

-- indicates no applicable maximum or secondary contaminant level.

\*\* Secondary maximum contaminant level (40 CFR, Part 143, 1995).

\*\*\* Lead is regulated by a Treatment Technique action level. The action level, which triggers public water systems into taking treatment steps if exceeded in more than 10% of tap samples, is 15µg/L.

"BMDL" = below method detection limits.

**Primary Drinking Water Standards** – These standards are enforceable and are often referred to as the maximum contaminant level or MCL. The MCL for a contaminant is the maximum permissible level in water that is delivered to any user of a public water system. Primary standards (MCLs) protect drinking water quality by limiting the levels of specific contaminants that can adversely affect public health and are known or anticipated to occur in public water systems. The primary standards are indicated on Table 6.1.

No MCLs were exceeded in the groundwater quality data collected for 1998. The action level for lead (not an MCL) was exceeded in one well (TD 68-42-806). The lead concentration in a water sample from well TD 68-42-806 was 28.7 µg/L., the action level is 15 µg/L. Lead concentrations above the action level are commonly associated with the corrosion of pumping equipment. As of 1998, no significant reoccurring instances of lead concentrations exceeding the action level have been detected in the Edwards Aquifer in the San Antonio region.

**Secondary Drinking Water Standards** – These standards are non-enforceable and are set for contaminants that may affect the aesthetic qualities of drinking water, such as odor or appearance. Table 6.2 is a list of the current secondary standards. Concentrations of the secondary standards listed on Table 6.2 are generally not exceeded in the freshwater portion of the Edwards Aquifer; however, concentrations of total dissolved solids (TDS), fluoride, and iron occasionally exceed the secondary standard. On occasions when concentrations exceed a secondary standard, the exceedance can be attributed to naturally occurring conditions.

Table 6.2 Secondary drinking-water standards.

Contaminant	Secondary Maximum Contaminant Level (SMCL)(mg/L)
Aluminum	0.05-0.2
Chloride	250
Color	15 color units
Copper	1.0
Corrosivity	Non-corrosive
Fluoride	2.0
Iron	0.3
Manganese	0.05
pH	6.5-8.5
Silver	0.10
Sulfate	250
Total Dissolved Solids (TDS)	500
Zinc	5

Data source: EPA, 40 CFR, Part 143, 1995.

The Authority will continue to monitor for these contaminants as well as many others in order to detect and investigate any occurrences of possible contamination to the aquifer. The Authority continues its programs to protect the excellent water quality of the aquifer through investigating groundwater contamination, and identifying and analyzing anomalous data from the Authority's aquifer-wide sampling program.

## 6.2 Freshwater/Saline-water Interface Study

The freshwater/saline-water interface of the Edwards Aquifer is a regional boundary between the fresh and saline portion of the aquifer and is defined by a mapped iso-concentration line representing 1,000 mg/l of total dissolved solids (TDS). Groundwater is commonly classified according to TDS concentrations, as shown in Table 6.3.

Table 6.3 Classification of groundwater quality based on total dissolved solids.

Description	TDS Concentration (mg/L)
Fresh	Less than 1,000
Slightly saline	1,000 to 3,000
Moderately saline	3,000 to 10,000
Very saline	10,000 to 35,000
Brine	More than 35,000

Source: Winslow and Kister, 1956.

The interface varies both laterally and vertically in portions of the aquifer. Locally this line is referred to as the freshwater/saline-water interface, or "bad-water line," which defines the farthest downdip extent of potable water (Pavlicek and others, 1987). The freshwater/saline-water interface is shown in Plates 2.1, 3.1 and 6.1. Water quality concerns related to the position and stability of the freshwater/saline-water interface have been expressed for years. The limited water quality data collected during and since the drought of record in the 1950's is inconclusive as to whether encroachment of saline water is likely.

South and southeast of the interface, water from the aquifer is slightly to moderately saline and contains moderate to large concentrations of dissolved chloride and sulfate. The interface varies both laterally and vertically, as determined in several wells near the boundary. Water from some wells north of the interface, and from all wells south of the interface contains dissolved hydrogen sulfide gas. In most wells along the interface, freshwater has been encountered in the upper portion and saline water in the lower portion of the Edwards Aquifer (Groschen, 1993; Reeves, 1971). Other wells along the interface have encountered the opposite vertical distribution, with saline-water zones overlying freshwater zones, particularly in the southern area of Medina County (J.R. Waugh, oral communication, 1997).

In 1985, a research study of the freshwater/saline-water interface was initiated by the former EUWD in cooperation with the USGS, TWDB and SAWS. A series of seven wells were drilled in the San Antonio area that transects the freshwater/saline-water interface to detect changes in water quality as the hydraulic head in the aquifer changes. This program was implemented in response to the concern that increased aquifer withdrawals might result in encroachment of saline-water into the aquifer freshwater zone. As part of the Authority's ongoing water quality program, monthly and other periodic samples have been collected and analyzed. Other samples are collected when certain spring-discharge criteria are met.

The possibility of saline-water encroachment and subsequent deterioration of water quality in the aquifer led to the construction of two additional water quality monitor well transects across the freshwater/saline-water interface. The monitor wells were drilled and tested by the Authority and USGS with the cooperation of local entities. These transects are located in the New Braunfels and San Marcos areas (Poteet and others, 1992). These transect wells have maintained relatively constant values of water quality with no significant changes. In 1998, the Authority, working in cooperation with SAWS and TWDB, provided funding to complete a transect of four wells in southeastern Uvalde County to study a structure known as the "Knippa

Gap" and the freshwater/saline-water interface in the Edwards Aquifer. During the studies conducted to date (1986 to present), the data indicate that normal changes in the aquifer water levels have little effect on the water quality in wells that are directly adjacent to the freshwater/saline-water interface.

### **6.3 Surface Water Quality Data**

Surface water quality data is collected within the catchment area at stations upstream of the EARZ. The surface water data collection sites are located within eight major stream basins that flow across and contribute significant groundwater recharge to the Edwards Aquifer within the EARZ in the San Antonio Region. These include from west to east, the Nueces River, Dry Frio River, Frio River, Sabinal River, Seco Creek, Hondo Creek, Medina River, and Blanco River. Data from this network of data collection sites can be used as a base level to evaluate the quality of water recharging the aquifer and the sensitivity of water quality to land use changes in various areas of the Edwards Aquifer region. Locations of data collection sites are illustrated in **Plate 6.1**. Laboratory analyses of the samples collected in 1998 (**Appendix B**) indicate no detectable concentrations of pesticides, herbicides, or volatile organic compounds.

## **7.0 SUMMARY**

The average estimated annual groundwater recharge to the Edwards Aquifer in the San Antonio region from 1934 through 1998 was approximately 683,100 acre-feet. Recharge in 1998 was approximately 1,142,300 acre-feet, which was well above the regional average. The lowest annual recharge of 43,700 acre-feet occurred in 1956, and the highest annual recharge of 2,486,000 acre-feet occurred in 1992.

Estimated annual discharge from the Edwards Aquifer through wells and springs in 1998 was 917,600 acre-feet. The lowest annual discharge through wells and springs was 388,800 acre-feet, which occurred in 1955. Spring discharge from the Edwards Aquifer for 1998 was calculated at 464,100 acre-feet or 51 percent of the total discharge. Groundwater pumping accounted for 453,500 acre-feet of water discharged from the Edwards Aquifer in 1998. In general, water level data during 1998 reflected a slight increase in water recharging the aquifer, as well as an increase in pumping relative to 1997.

Results of the Authority's 1998 water quality monitoring program illustrate the continued excellent quality of water in the Edwards Aquifer. In 1998, the Authority collected water quality samples from wells, springs and stream basins, which were analyzed for major ions, nutrients, minor element metals, pesticides, herbicides, and VOC's. Laboratory analyses of samples from several wells contained minor element metal concentrations slightly above the MDL. No compounds were detected in 1998 above MCL concentrations. Laboratory analyses of the surface water samples collected in 1998 indicated no detectable concentrations of pesticides, herbicides, or VOC's. Overall, results of the 1998 water quality sampling and analysis program illustrate the continued excellent quality of water in the Edwards Aquifer.

## 8.0 DEFINITIONS

Technical terms and abbreviations used in this report are defined as follows:

<u>Acre-foot (ac-ft)</u>	The quantity of water required to cover one acre to a depth of one foot, equivalent to 43,560 ft <sup>3</sup> (cubic feet), about 325,851 gal (gallons), or 1,233 m <sup>3</sup> (cubic meters).
<u>Aquifer</u>	A body of rock that contains sufficient saturated permeable material to conduct groundwater and to yield economically significant quantities of groundwater to wells and springs.
<u>Artesian well</u>	A well tapping confined groundwater. Water in the well rises above the level of the confined water-bearing strata under artesian pressure but does not necessarily reach the land surface.
<u>Artesian zone</u>	An area where the water level from a confined aquifer stands above the top of the strata in which the aquifer is located.
<u>Bacteria</u>	Microscopic unicellular organisms, typically spherical, rod-like, or spiral and threadlike in shape, often clumped in colonies. Some bacteria are pathogenic (causing disease), while others perform an essential role in nature in the recycling of materials (measured in colonies/100 ml).
<u>Conductivity</u>	A measure of the ease with which an electrical current can be caused to flow through an aqueous solution under the influence of an applied electric field. Expressed as the algebraic reciprocal of electrical resistance (measured in microSiemens per centimeter ( $\mu\text{S}/\text{cm}$ ) at ambient temperature). Generally, in water the greater the total dissolved solids content, the greater the value of conductivity. See also Specific conductance.
<u>Confined aquifer</u>	An artesian aquifer or an aquifer bound above and below by impermeable strata, or by strata with lower permeability than the aquifer itself.
<u>Discharge</u>	The volume of water that passes a given point within a given period of time.
<u>Drainage basin</u>	An area bounded by a divide and occupied by a drainage system. It consists of a surface stream or a body of impounded surface water together with all tributary surface streams and bodies of impounded surface water.

<u><b>Edwards Underground Water District</b></u>	The regional governmental entity that preceded the Edwards Aquifer Authority.
<u><b>Freshwater/saline-water interface</b></u>	The interface or area that separates total dissolved solids (TDS) values less than 1,000 mg/L (freshwater) from TDS values greater than 1,000 mg/L (saline-water). Commonly referred to as the “bad water line.”
<u><b>Gauging station</b></u>	A particular site that systematically collects hydrologic data such as streamflow, springflow or precipitation.
<u><b>Groundwater divide</b></u>	A ridge, or mound in the water table or other potentiometric surface from which the groundwater moves away in both directions.
<u><b>Micrograms per liter (<math>\mu\text{g/L}</math>)</b></u>	A unit for expressing the concentration of chemical constituents in solution as mass (micrograms) of solute per unit volume (liter) of water. 1,000 micrograms per liter are equal to 1 milligram per liter.
<u><b>Milligrams per liter (mg/L)</b></u>	A unit for expressing the concentration of chemical constituents in solution as mass (milligrams) of solute per unit volume (liter) of water. 1,000 milligrams per liter are equal to 1 gram per liter.
<u><b>Potentiometric surface</b></u>	An imaginary surface representing the total head of groundwater and defined by the level that water will rise in a well.
<u><b>Real time data</b></u>	Instantaneous or near-instantaneous information used to monitor a current condition such as precipitation, stream flow, spring discharge, etc.
<u><b>Recharge</b></u>	The process involved in absorption and addition of water to the zone of saturation.
<u><b>Recharge zone</b></u>	The area in which water infiltrates into the ground and eventually reaches the zone of saturation in one or more aquifers.
<u><b>Specific conductance</b></u>	A measure of the ability of an aqueous solution to conduct an electrical current. Specific conductance is the given value of conductivity adjusted to a standard temperature of 25°C. Expressed in microsiemens per centimeter ( $\mu\text{S}/\text{cm}$ ). See also Conductivity.
<u><b>Ten-year floating average</b></u>	The calculated mean of the current year plus the previous nine years in a graph.
<u><b>Total dissolved solids (TDS)</b></u>	The concentration of dissolved minerals in water, expressed in units of milligrams per liter (mg/L).

<b><u>Transect wells</u></b>	A group of water quality monitoring wells positioned in a site to monitor water quality changes, such as across the freshwater/saline-water interface.
<b><u>Unconfined aquifer</u></b>	An aquifer, or a portion of an aquifer, with a water table and containing groundwater that is not under pressure beneath relatively impermeable rocks.
<b><u>Underflow</u></b>	The movement of water flowing beneath the land surface within the bed or alluvial plain of a surface stream.
<b><u>Water table</u></b>	The interface between the zone of saturation and the zone of aeration, where the surface pressure of unconfined groundwater is equal to the atmospheric pressure.
<b><u>Water level observation well</u></b>	A water well used to measure the water level or potentiometric surface of water-bearing strata such as the Edwards Aquifer, Leona Gravel Aquifer, and Lower Glen Rose (Trinity) Aquifer.
<b><u>Zone of aeration</u></b>	The subsurface zone where the voids and pore spaces are filled with water under less pressure than that of the atmosphere and air.
<b><u>Zone of saturation</u></b>	The subsurface zone in which all voids and pore spaces are filled with water under pressure greater than that of the atmosphere.
