Introduction

The Balcones Fault Zone Edwards Aquifer in south central Texas is one of the most permeable and productive aquifers in the United States. The San Antonio segment of the aquifer, which is the subject of this report, extends from the groundwater divide near Brackettville in Kinney County, east to the city of San Antonio in Bexar County, then northeast to the groundwater divide near Kyle in Hays County—a distance of approximately 180 miles (Figure 1). The aquifer is the primary source of water for approximately 1.7 million people in the region (<http://quickfacts.census.gov/qfd/>), and provides most of the water for agriculture and industry. In addition, the aquifer discharges through a series of large springs that provide aquatic habitat for a number of threatened and endangered species. Springflow also provides a significant portion of water for downstream interests in the Guadalupe River basin.

The Edwards Aquifer Authority (the Authority) was created by the Texas Legislature in 1993 to replace the Edwards Underground Water District (EUWD) as a special regional water management district in charge of the San Antonio segment of the Edwards Aquifer. The Authority's jurisdictional area encompasses all or parts of eight counties, including Uvalde, Medina, Atascosa, Bexar, Comal, Guadalupe, Hays, and Caldwell counties (Figure 1).

The Legislature mandated that the Authority take all necessary measures to effectively manage the resource to ensure domestic and municipal water supplies, to promote the operation of existing agriculture and industry, to protect terrestrial and aquatic habitat, and to sustain the economic development of the region. To accomplish these goals, the Authority is vested with all of the “powers, rights, and privileges necessary to manage, conserve, preserve, and protect the aquifer, and to increase the recharge of, and prevent the waste or pollution of water in, the aquifer” [*the Edwards Aquifer Authority Act, as amended*]. The Act is available in pdf format at www.edwardsaquifer.org. Pursuant to this mandate, the Authority has undertaken the Edwards Aquifer Optimization Program (EAOP). This program is a series of interrelated, mission-

directed biologic and hydrogeologic research studies known as Optimization Technical Studies (OTS). These OTS are designed to evaluate potential technical options for the optimization of the Edwards Aquifer. Data and information from these studies provide aquifer managers with the tools necessary to make well-informed decisions aimed at benefiting aquifer users while preserving the environments supported by the aquifer, including Comal and San Marcos springs, and downstream aquatic habitats.

The initial OTS were conceived by the Authority's Technical Advisory Group (TAG), staff, and consultants and subsequently documented by Todd Engineers in May of 1999, in *Optimization Technical Studies in Support of the Edwards Aquifer Optimization Program*. The origin of the Synoptic Water Level Program (SWLP) is discussed in this document. Specifically, the SWLP is not an optimization technical study, but rather a support study designed to "... provide data for water level contour maps, flowpath studies, and the management computer model construction." (Todd Engineers, 1999).

Beginning in 1999, staff from the Authority, San Antonio Water Systems (SAWS), United States Geological Survey (USGS), Edwards Aquifer Research and Data Center (EARDC), Texas Water Development Board (TWDB), and Barton Springs/Edwards Aquifer Conservation District (BS/EACD) have measured aquifer water levels in more than 220 wells (on average) throughout the study area, for each synoptic event. Wells are generally measured within a one-week period for each event.

The synoptic measurements reported in this study are taken within the San Antonio segment of the Balcones Fault Zone Edwards Aquifer in Kinney, Uvalde, Medina, Atascosa, Bexar, Caldwell, Comal, Guadalupe, and Hays counties. Additional measurements from parts of the Barton Springs segment of the Edwards Aquifer in Travis and Hays counties, which are under the jurisdiction of the Barton Springs Edwards Aquifer Conservation District, are also included in this report.

Many synoptic studies have been performed prior to this investigation. The most recently published study by Maclay et al. (1980) is comprehensive with respect to information regarding aquifer parameters, such as recharge, discharge, specific capacity, and aquifer test data, in addition to synoptic water level data. The Maclay study also includes a potentiometric (water level contour) map covering approximately the same geographic area as does this investigation. Synoptic investigations prior to Maclay's work are listed in Table 1. Whereas some previous investigations include additional aquifer parameter data and may be more comprehensive in nature, the current investigation documents more individual water level measurement events (16 events total) than do other listed investigations.

In keeping with the original intent of the OTS with regard to the SWLP, the purpose of this

report is to provide interested parties a source for the synoptic water level data (Appendices A and B) and potentiometric surface maps (Appendix C) that display an interpretation of the data for each event. Additionally, the synoptic data provide a useful support tool for other optimization studies related to flowpath understanding and model development.

Each of the SWLP events documented herein is represented as a potentiometric surface map. Each map is produced from data point (water level) values without consideration of other parameters, such as recharge, discharge, or geologic structure, which may cause localized variations in the potentiometric surface. These parameters are summarized in the Authority's annual *Hydrologic Data Report*, available in pdf format from the Authority's Website at www.edwardsaquifer.org.

*Source: Maclay et al., 1980, Table 3.

Of the 16 SWLP events covered in this report, five events (July 2000, October 2001, November 2002, July 2004, and December 2004) plot the recharge and artesian zones of the aquifer as separate data sets and are referred to as two-system maps. These events are plotted as two-system maps because of their representation of conditions that are unique to the synoptic program. Specifically, the two-system maps represent the following aquifer conditions:

- Lowest (SWLP) water level event as recorded at index well J-17 (645' msl, July 2000),
- Highest (SWLP) water level events as recorded at index well J-17 (697' msl, November 2002 and 701' msl, December 2004),
- Highest (SWLP) water level event as recorded at index well J-17, with the maximum number of data points (687' msl, July 2004), and
- SWLP water level closest to the mean for the period July 1999–December 2004 as recorded at index well J-17 (675' msl, October 2001).

The remaining 11 SWLP events are plotted as a single system, wherein the data points are combined across the recharge and artesian zones of the aquifer.

The SWLP began in July of 1999, as a three event per year effort to capture a “snapshot” of water levels across the entire reach of the San Antonio segment of the Balcones Fault Zone Edwards Aquifer and the southernmost extent of the Barton Springs Segment of the Balcones Fault Zone Edwards Aquifer (Figure 1). After October 2003, the program was modified by a reduction of the number of annual regionwide events from three to one. This modification provides the exception that additional regionwide events would be performed only if water levels at the Bexar County index well (J-17) were to exceed or fall below previously recorded levels for SWLP measurement events.

The modified SWLP program was initiated after a review of preliminary maps indicated that no significant changes in the potentiometric surface maps were evident for changes in aquifer levels within the range of obtained data. Reducing the number of annual synoptic events allowed the

Authority an option to pursue a more refined approach to synoptic data gathering in the form of “focused” synoptic events. These focused events allow concentrated data to be gathered from smaller geographic areas in an effort to reduce data gaps, resulting in a more representative picture of localized variations in the shape of the water surface. For example, areas such as the Knippa Gap, Cibolo Creek, and the Hays County groundwater divide benefit from a more focused investigation, allowing groundwater behavior in these areas to be better understood. In addition, this focused approach increases resolution within the more limited study areas and might provide insight regarding other aspects of the system, such as the Edwards Trinity groundwater interaction along the northern boundary of the Edwards Aquifer Recharge Zone.

As a result of the modified synoptic program, only one measurement event was planned for calendar year 2004; however, the water level at index well J-17 exceeded the previous synoptic high of 697 feet (recorded in November 2002) above mean sea level (msl). The new SWLP high of 701 feet msl occurred after completion of the July 2004 SWLP measurement event. As such, calendar year 2004 consists of two SWLP events, the first in July and the second in December. The July event represents the scheduled annual synoptic event, whereas the December event was performed so that near record high water levels in the aquifer might be recorded. Water levels at the Bexar County index well J-17 were recorded at 701 feet above msl for the December 2004 event, four feet above the previous synoptic program high of 697 feet above msl and close to the historical high of 703 feet above msl for the period of record (1934–2004).

Continuation of the SWLP will aid in the general understanding of water movement within the system, thereby contributing to other OTS objectives, including improved modeling, protection, and optimization of the aquifer. The Authority is currently developing a series of focused synoptic studies, while performing at least one regional synoptic event annually. Should the level of the Edwards Aquifer as measured at index well J-17 exceed or fall below any previously recorded SWLP level, additional regional events will be performed.

Hydrogeology of the Edwards Aquifer

The Balcones Fault Zone Edwards Aquifer in south central Texas is one of the most permeable and productive aquifers in the United States. The San Antonio segment of the aquifer, which is the subject of this report, extends from the groundwater divide near Brackettville in Kinney County, east to the city of San Antonio in Bexar County, then northeast to the groundwater divide near the city of Kyle in Hays County. This segment of the aquifer stretches approximately 180 miles in length and varies in width from 5 to 40 miles. The aquifer is the primary water source for much of the area, including the City of San Antonio.

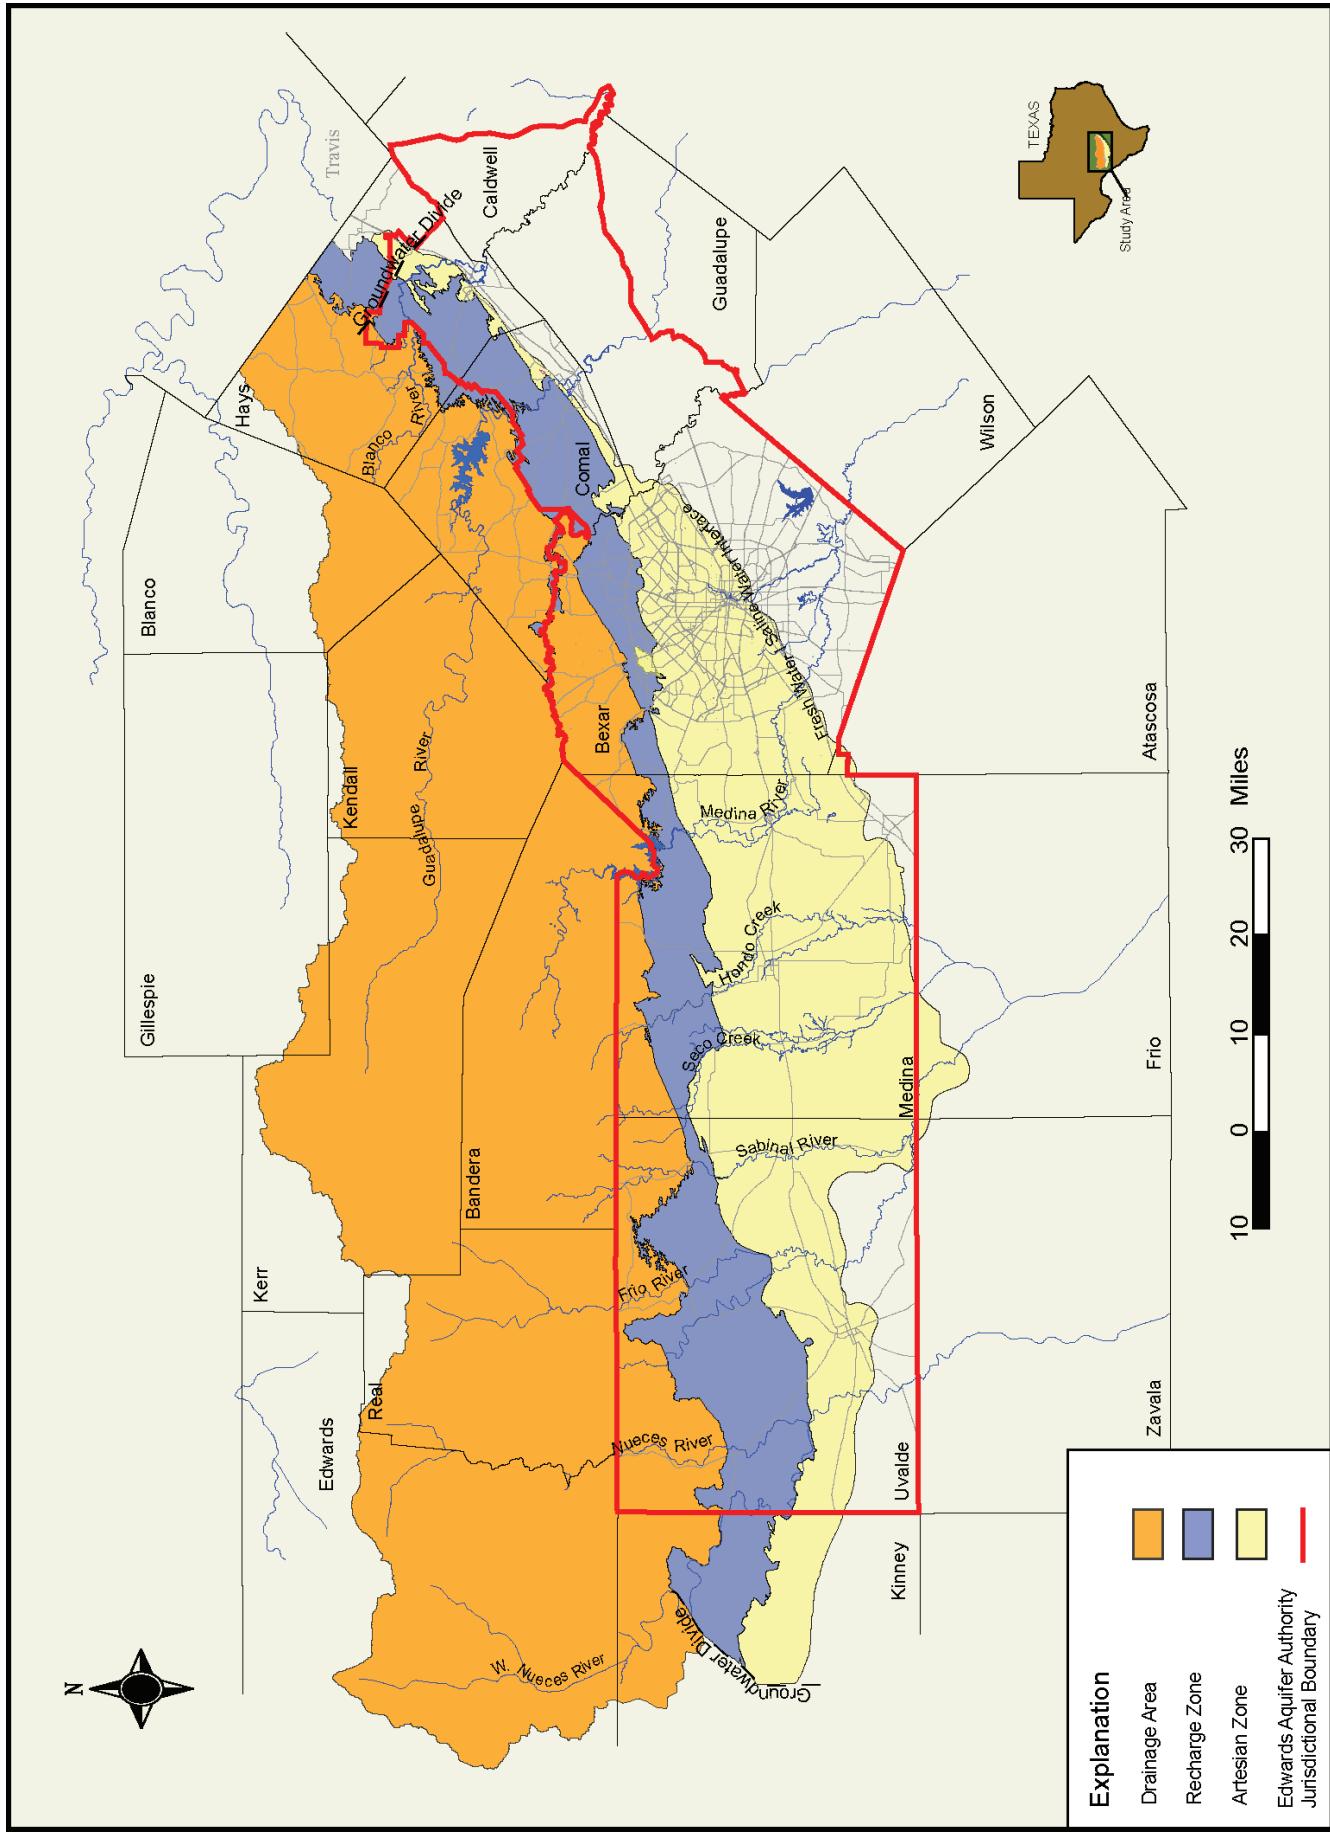

The Edwards Aquifer is contained within the Cretaceous-age Edwards Group limestone (Edwards Limestone) and associated units. The aquifer is generally capped by the Del Rio Clay (upper confining unit) and overlies the Glen Rose Formation (lower confining unit). The Edwards Limestone and associated units range from 450 to more than 600 feet in thickness in the region. A series of faults in the Balcones Fault Zone has exposed the Edwards Limestone at the surface along the southern boundary of the Texas Hill Country. This area of exposed Edwards Limestone is frequently referred to as the recharge zone. South and east of the recharge zone, downfaulting has dropped the Edwards Limestone to great depths below the surface. The area where the Edwards Limestone is located below the surface is generally referred to as the artesian zone of the aquifer. Figure 1 shows the study area and details discussed herein.

Water circulates through the Edwards Aquifer as part of the hydrologic cycle from recharge areas to discharge points (springs and wells). Approximately 1,250 square miles of Edwards Limestone is exposed

at the ground surface (recharge zone). Streams flow south from the drainage area (the Texas Hill Country) and lose all or most of their baseflow as they cross the recharge zone. In addition, a portion of the rain that falls directly on the recharge zone also enters the aquifer. Groundwater moves through the aquifer and ultimately discharges from a number of locations, such as Leona Springs in Uvalde County; San Pedro and San Antonio springs in Bexar County; Hueco and Comal springs in Comal County; and San Marcos Springs in Hays County. In addition, domestic, municipal, irrigation, and industrial wells throughout the region withdraw water from the aquifer. The residence time of water in the aquifer ranges from a few hours or days to many years, depending on depth of circulation, location, and other aquifer parameters.

The Edwards Aquifer is a karst aquifer characterized by the presence of sinkholes, sinking streams, caves, springs, and a well-integrated subsurface drainage system. It is one of the most productive groundwater systems in the United States, characterized by extremely productive water wells and high spring discharges. The aquifer exhibits extremely high (cavernous) porosity and permeability that is characteristic of many karst aquifers. The Edwards Aquifer transmits very large volumes of water, enabling groundwater levels to respond quickly to rainfall (recharge) events. As a result, delineation of flowpaths can be a difficult process in the aquifer. The current synoptic study will be refined to better delineate flowpaths and anomalous groundwater levels in the aquifer on a localized scale. The synoptic data may also be used to help determine contamination pathways, thus improving the ability to monitor and remediate contaminant events.

Figure 1. San Antonio Segment of the Balcones Fault Zone Edwards Aquifer

Data Acquisition, Validation, and Analyses

Background

Initially (1999–2003), SWLP data were collected three times annually on the basis of aquifer-related events, which are summarized below:

- (1) Pre-irrigation (late January to early February), which often may represent a high level for the year;
- (2) Post-irrigation (mid- to late July); and
- (3) Fall (late October to early November).

For the historical period of record (1934–2004), the mean water level elevations at Bexar County index well J-17 are highest during the pre-irrigation time period. Post-irrigation water levels are close to the mean low elevation for the period of record. Aquifer levels for the fall synoptic event are generally representative of recovery from the high demand months of summer. See Figure 2 for historical daily average water levels at index well J-17.

For the SWLP events reported herein, the number of wells measured across the region ranges from 158 (December 2004) to 242 (October 2003) per event. The average number of wells measured per event is 221. For each event a small percentage of the measured wells were not used in construction of the potentiometric surface maps because of discrepancies with their respective data values. The data sets in Appendix A summarize all wells measured for each synoptic event. Those listed in Appendix B provide a summary of wells not used in construction of the potentiometric surface maps. Well types measured include domestic, observation, municipal, industrial, and irrigation wells. Well distributions encompass the recharge, artesian, and, in some cases, the saline zones of the Edwards Aquifer.

Data Acquisition and Validation

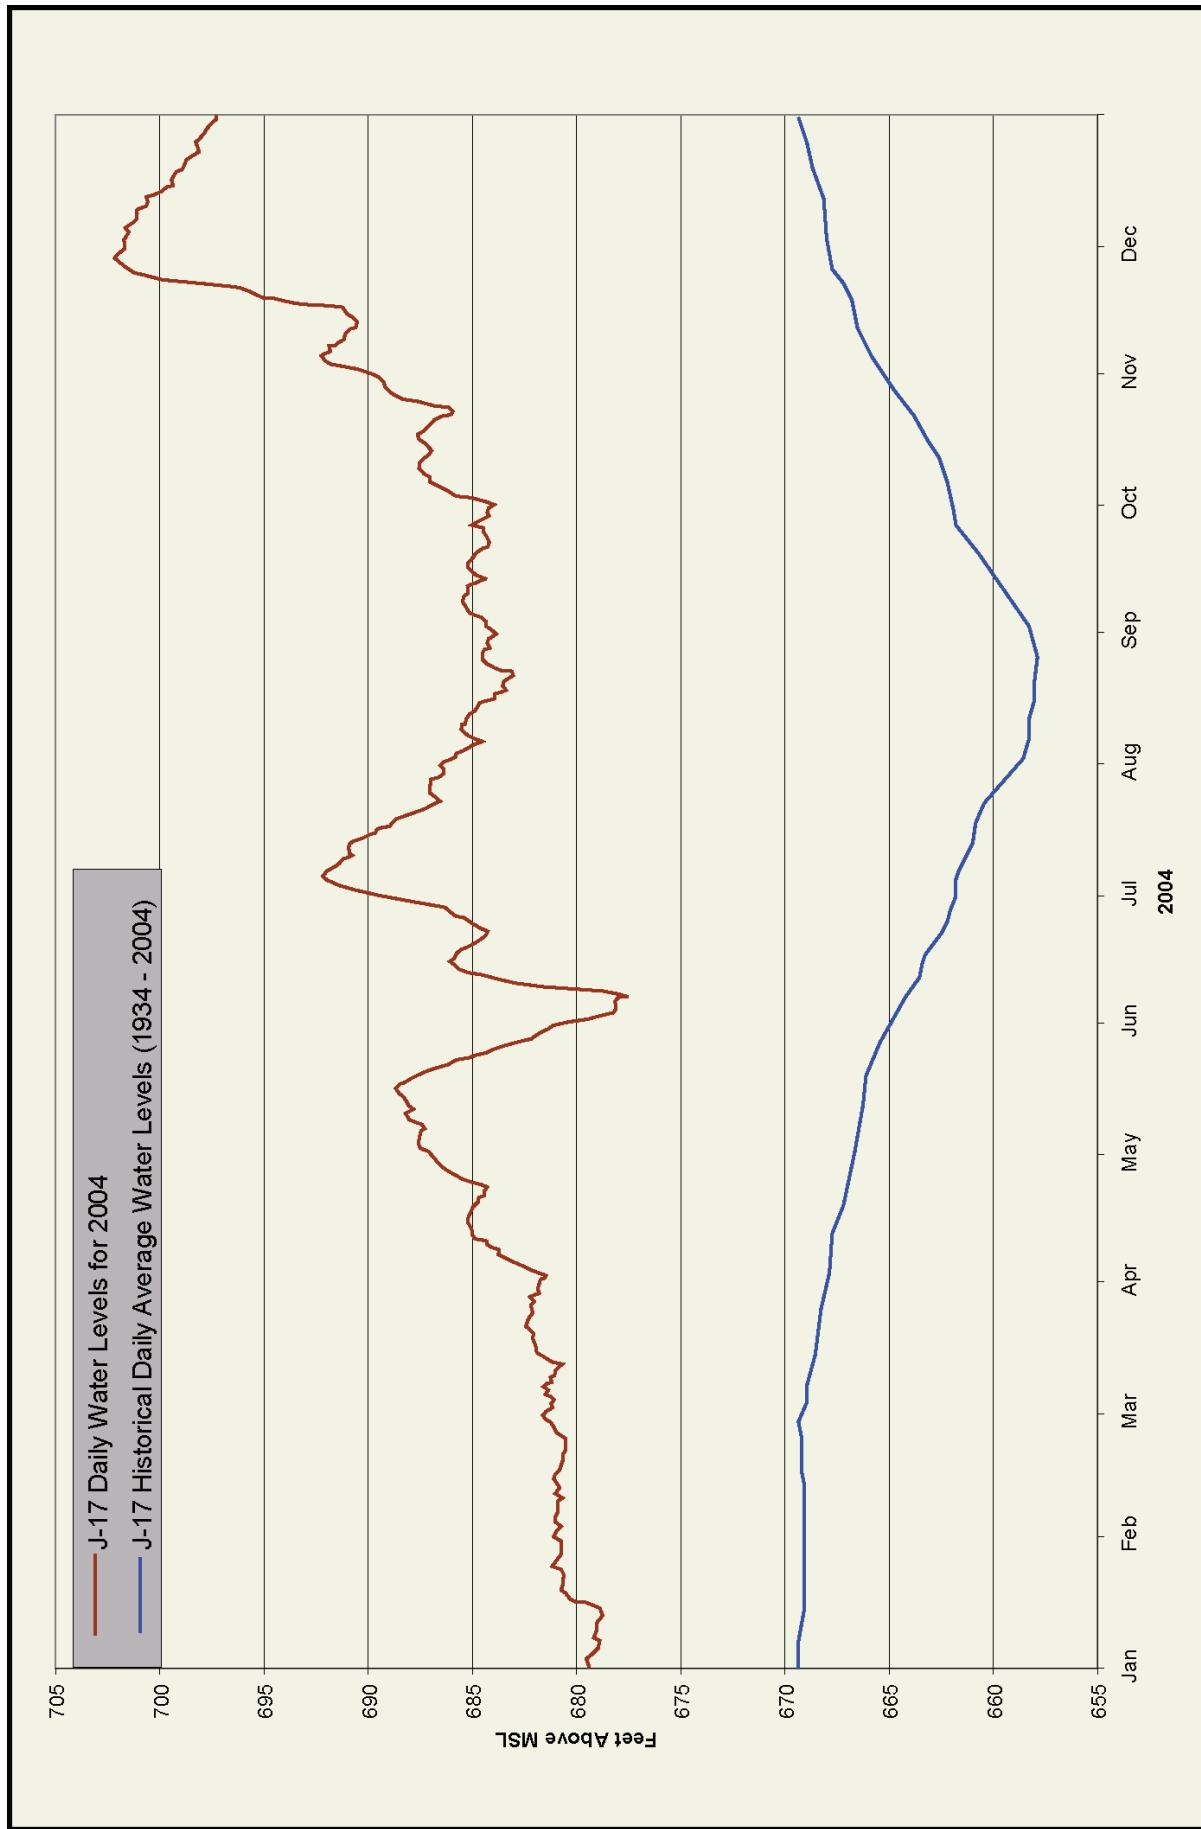

Synoptic water level data are initially acquired in the field using one of the following devices: steel tape, electric line, pressure gauge, or continuous recorder. Generally speaking, the steel tape is the most accurate device for collecting water level information. As measurements are taken, they are recorded in the field on a water level form. These data are subsequently transferred into

an electronic database by Authority staff. Once available electronically, data points are validated for location and elevation accuracy. Location accuracy is validated through the use of ESRI ArcGIS® software. Wells are plotted with aquifer boundaries and county boundaries together on a single map. Incorrectly located wells were either corrected or deleted from the data set for the particular synoptic event. After the “X and Y” location values for each well were validated, groundwater elevations (“Z” values) were validated.

Validation of elevations is accomplished by posting all elevation values for each event on the map and comparing adjacent elevations for relative agreement. Data points with suspicious values were either corrected or not used in compiling the potentiometric surface maps. For example, wells exhibiting apparently anomalous groundwater elevations compared with surrounding wells were examined for measurement errors or other conditions that may cause an apparently anomalous value. If the data point could not be corrected after review of field notes and calculations, the data point in question was not used in map development. After completion of this process, initial potentiometric contours were subsequently generated and checked against point elevations again. This iterative process was conducted for each map and, in some cases, multiple times for various target data groups.

So that artesian zone water levels might be interpreted more accurately, other wells (data points) removed from the data set prior to the development of potentiometric maps include certain saline zone wells. In addition, well number RP-70-38-902 in the recharge zone in Kinney County and wells YP-69-35-401, YP-69-35-804, and YP-69-35-602, in the recharge zone of Uvalde County were not used in compiling potentiometric maps. The Kinney County well did not have sufficient surrounding water level data to justify its use, whereas the Uvalde County recharge zone wells were not used because of questionable water level behavior in these wells, as well as insufficient surrounding water level data. Two of the Uvalde County wells appear to be hydraulically connected to the Frio River, whereas

Figure 2. Comparison of the Historical Daily Average Water Level for the Period of Record, 1934–2004 and the Calendar Year 2004 Daily High Water Level at the Bexar County Index Well, J-17 (AY-68-37-203)

the third does not show any significant water level fluctuations. These wells do not appear to be sensing water levels from the Edwards Aquifer.

Well Surveying and Identification

Many of the wells used for gathering synoptic water level data within the study area initially did not have accurate geographic or elevation information. As such, many wells required coordinate and elevation surveys in order to improve the quality of the data set with respect to locations and groundwater elevations. Therefore, the Authority contracted with a Registered Professional Land Surveyor to perform coordinate and elevation surveys on SWLP wells with missing or questionable location and elevation data. Concurrent with the SWLP well survey effort, additional wells were surveyed under the same project in order to establish accurate location and elevation data for wells used as calibration points for an aquifer-modeling project. Approximately 400 wells were therefore identified by the Authority and surveyed by a contractor, or by staff in some cases, between calendar years 2002 and 2003. Wells were surveyed for location and elevation accuracy using a surveyor's-grade global positioning system (GPS) to collect latitude, longitude, and elevation data at each well. The location data were reported in degrees, minutes, and seconds in the NAD83 horizontal coordinate system, and the elevation data were reported in the NAVD88 vertical coordinate system accurate to within three inches. SAWS production wells were surveyed by the SAWS professional survey crew (Denise Renaghan, SAWS, written communication).

The BS/EACD staff provided the locations and elevations for a series of monitoring wells in the BS/EACD's jurisdiction. The wells within the BS/EACD were surveyed using a Trimble GPS Pathfinder Pro XRS unit, which receives a beacon signal and differentially corrects for position in real time. The BS/EACD location data were reported in the WGS84 or NAD83 horizontal coordinate system, and the elevation data were reported in the NAVD88 vertical coordinate system, accurate within one to three feet (Stefani Helcamp, BS/EACD, written communication).

To be useful to the investigation, in addition to the requirement of accurate location and elevation

data, each data point or well must have a unique identifier. Wells for this project are identified primarily by using the TWDB well numbering system (see Appendix D for additional information regarding the TWDB well numbering system). Wells without a state well number were assigned a unique pseudo-number on the basis of the well numbering system discussed in Appendix D.

Data Analyses

Once validated, data sets for individual events were plotted using Golden Software's Surfer® Version 8 surface mapping software. Plotting involves grouping point data into groups on the basis of geographic location. These groups are referred to herein as target areas. Maps for which the recharge and artesian zones were plotted separately (two-system maps) typically had four target areas for the recharge zone and four, or sometimes five, target areas for the artesian zone. Maps for which the recharge and artesian zones were plotted together had a total of four target areas. The target data sets provide a more representative picture of the area modeled by limiting the area of interest to those that are adequately populated for the geographic area being modeled. Generally these geographically limited data sets provide improved results when using the kriging algorithm in Surfer®, as compared with plotting the entire region as a single data group. Figures 3 and 4 demonstrate this approach of using target data sets for modeling the data. In some cases, a limited number of wells may appear in two target areas for continuity between data sets. For example, a few wells along the Bexar/Medina county boundary were used in target data sets T1 and T2 of Figure 4.

Once plotted, potentiometric contours were exported to ArcGIS® and overlaid with county and aquifer boundaries. The combined geographic information was then exported into Adobe Illustrator® for final graphic presentation, where data points were checked against equipotential lines in the map. The maps are representative of the general potentiometric surface in the aquifer at the time that the synoptic data were gathered. The completed potentiometric surface maps are located in Appendix C for all synoptic events.

Figure 3. Two-System Maps Target Data Groups

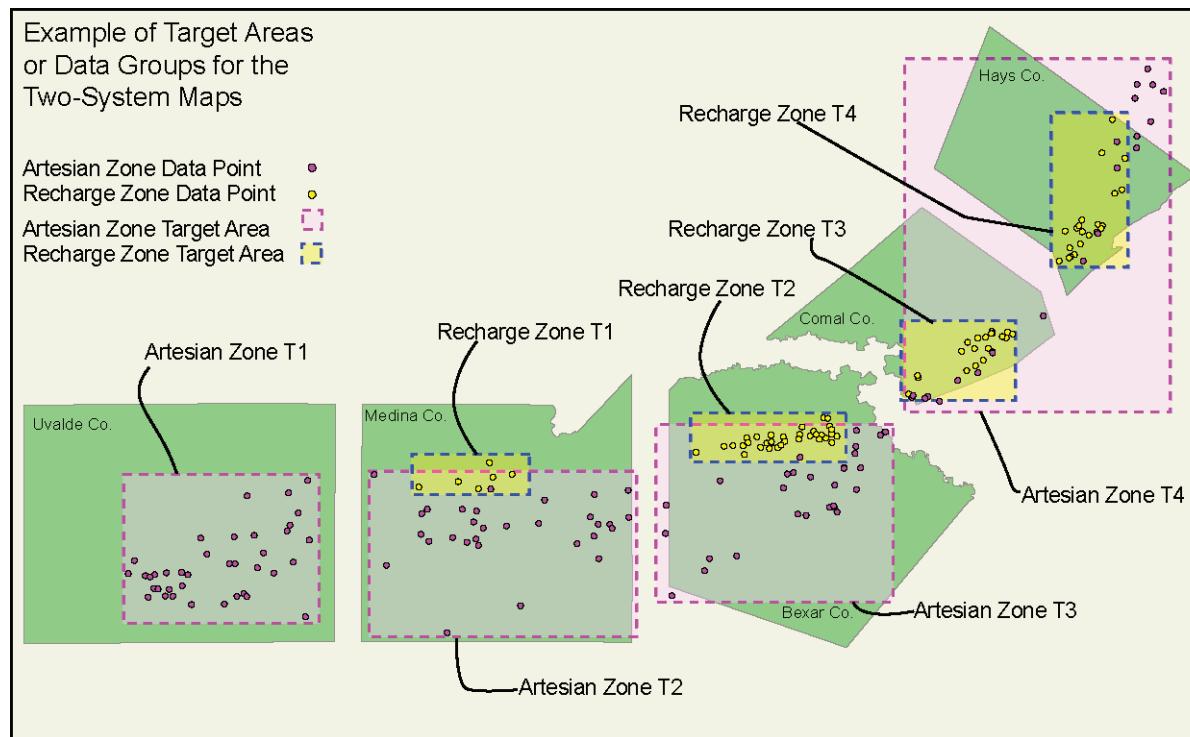

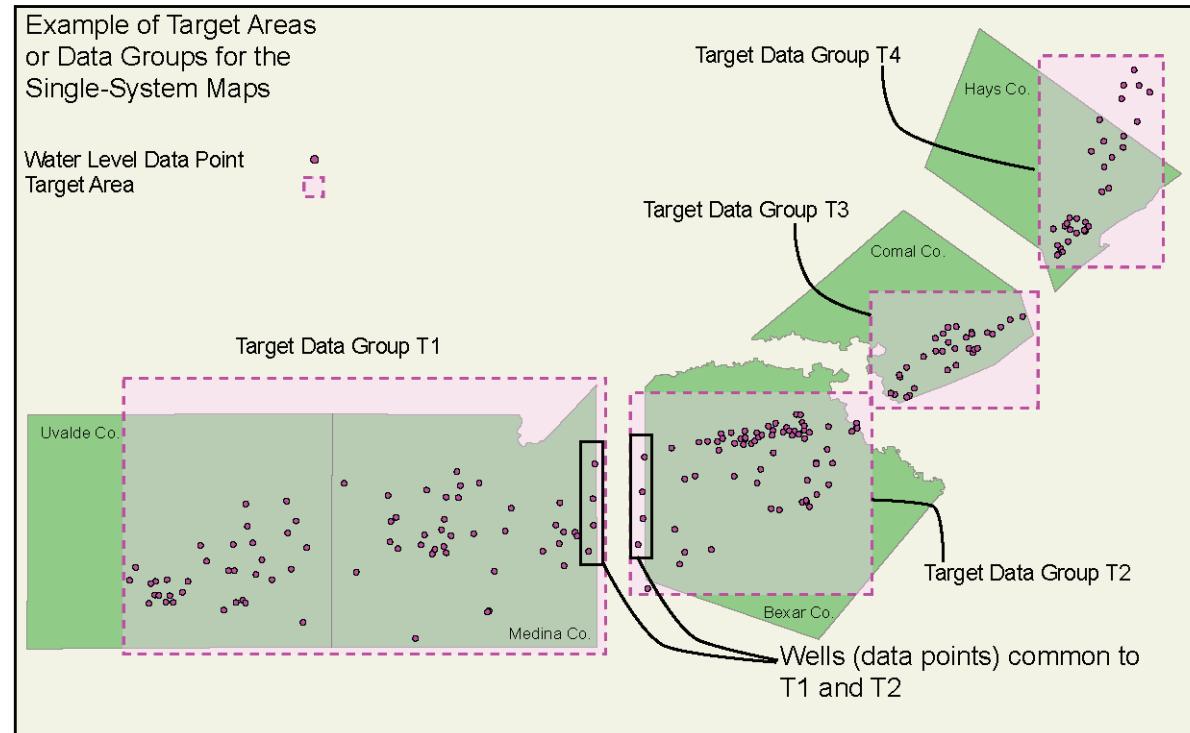

Figure 4. Single-System Maps Target Data Groups

Data Gaps

All of the data sets have some areas with data gaps, or lack of groundwater elevation points, within them. Although this issue has been reduced in severity during the evolution of the program, the following areas would benefit greatly from additional detail:

- Kinney County—All (currently only one well is regularly measured here).
- Uvalde County—Recharge zone (all), artesian zone along the east and west boundaries of Uvalde County.
- Medina County—Recharge zone in the west and far-east parts of the county, artesian zone in the west, south, and southeast parts of the county. Also that part of the artesian zone south of the Medina County line.
- Bexar County —Recharge zone northeast and far-west parts of the county, artesian zone in the west-central part of the county.
- Comal County—Recharge zone in north, northwest, and northeast parts, and artesian zone in the far-southeast end.
- Hays County—Recharge zone coverage is generally sparse, and the study would benefit from additional data points throughout this area; artesian zone in the central parts of the county.

Observation of the SWLP data gaps has spurred interest in focusing the SWLP to data collection within a single county or limited parts of multiple counties. Groundwater elevations could potentially be collected across the artesian and recharge zones, as well as the southern end of the drainage area under this program. However, obtaining well location data, survey data, and permissions to access wells in this manner is time consuming, effectively reducing the number of data collection events that may be performed annually. For example, obtaining access to an adequate number of wells to perform a high data density focused synoptic event could take between one and two years.

Sources of Error

Although significant effort has been made toward data validation and error reduction, the potential for errors within the data set remains. Detailed well logs for many of the measured wells do not exist, nor is it feasible to obtain such information. Many of the wells are not fully penetrating, and a few may be completed through more than one water-bearing formation (i.e., Edwards-Trinity, or Austin-Buda-Edwards). Wells completed in multiple formations could result in a groundwater elevation measurement that reflects an anomalous value with respect to the Edwards Aquifer. In addition, wells that are not fully penetrating may exhibit differing water levels between the top and bottom of the Edwards Limestone for some areas within the region. It is also possible that some wells in the recharge zone may be influenced by the underlying Trinity Aquifer, which may affect groundwater elevations at that point. Additionally, the potential for measurement error always exists, as do incorrect survey data or wells affected by drawdown due to pumping. Another possible issue is related to response time from recharge events. Recharge zone wells may respond almost immediately in some cases to a recharge event, whereas artesian zone wells may not respond for a period of days or not at all. Recharge zone wells may also respond with a sharp increase in water level, whereas artesian zone wells are usually “buffered” in their response and may show only a small percentage of increase in water level. The response issue would be of significance if a heavy rainfall event occurred during the measurement process. All of the listed error sources would influence the two-system maps more significantly than the single-system maps.

Study Results

To date, the SWLP has yielded a comprehensive set of regional potentiometric surface maps for wide-ranging aquifer conditions. Between 1999 and 2004, water levels in the Edwards Aquifer fluctuated 56 feet, from a low of 645 feet msl to a high of 701 feet msl, as measured at Bexar County index well J-17. The potentiometric surfaces represented by the maps may be correlated with index wells J-27 in Uvalde and J-17 in San Antonio, as well as with springflow rates at Comal and San Marcos springs. These water levels and springflow rates are included on each map for each synoptic measurement event, satisfying the objective of providing good calibration points (water levels) for aquifer modeling, as well as producing potentiometric (water level contour) maps. The maps are also useful for delineation of the general shape of the aquifer's water surface over a wide range of conditions.

Study results indicate flow across the region to be from west to east between Uvalde, Medina, and Bexar counties. In Bexar County, the groundwater gradient takes a more northeasterly direction and continues through Hays County. However, gradients become slightly more complex for the two-system maps, where recharge zone flow directions are much more variable and change by county. In addition, the two-system maps provide better detail regarding groundwater divide definition along the Hays and Travis county boundary. Whereas these maps may not reveal many of the potential local variations that most likely occur in the groundwater gradient across the region, they do provide representative detail for the number of data modeled. The lack of local resolution is due primarily to the number of data points versus the size of the area modeled. This lack of local resolution becomes apparent when comparing the detail obtained in the recharge zone of Bexar County with that of other areas modeled in this study.

Some areas within the maps exhibit notable variations in groundwater gradient behavior. As mentioned for the two-system maps, the recharge and artesian zones frequently exhibit significantly different groundwater levels and gradients in many areas. Furthermore, the two-system maps indicate northern Hays and southern Travis counties as the

probable location of a groundwater divide. For all of the maps, the Knippa Gap area is another area of interest. Water levels to the west of the Knippa Gap appear to be consistently higher and show little fluctuation when compared with levels in Medina, Bexar, Comal, and Hays counties.

Developing potentiometric surface maps with more data points for a smaller area would enhance resolution and most likely improve the overall understanding of local variations in groundwater gradients across the area. Another possibility is to plot the existing data at an enhanced scale. In some areas doing so would result in significantly more detail. The recharge zone in Bexar County is a good candidate area. The lack of resolution with regard to localized variations makes a focused synoptic program appealing. The focused approach will provide greater detail regarding local variations in the potentiometric surface by increasing data coverage per unit of area. As may be seen in the maps (Appendix C), data coverage is sparse in most areas. The area with the most coverage is the recharge zone of Bexar County.

Two-System Maps

As discussed previously, five of the SWLP potentiometric surface maps model recharge and artesian zones separately or as two systems. In general, this approach provides a more detailed representation of variations in groundwater gradients between the artesian and recharge zones of the aquifer. The most prominent differences between the two-system and single-system maps appear to be in the area of Comal and San Marcos springs for all five maps. Another interesting difference between artesian and recharge zone behavior occurs in the two-system map for Medina County for July and December 2004. Just east of the central part of the county, the recharge zone gradient varies by roughly 90° from the artesian zone gradient. The December 2004 map also provides good detail in the Bexar County recharge zone, indicating some of the local variations in groundwater gradient present in this area.

As previously mentioned, data-point resolution is fairly high in north Bexar County. The resulting

detail is summarized in Figure 5, where contours for the Synoptic Program's high and low water level values are displayed simultaneously for this area. The synoptic low value at index well J-17 is 645 feet msl, recorded in July 2000. The synoptic high value at index well J-17 is 701 feet msl, recorded in December 2004. In Figure 5, red contours represent the high value, whereas blue contours represent the low value. Note the contour lines adjacent to points A and B in the figure. Starting at these points moving along a north-northwest trend line, the contours curve in opposite directions between the two events. This change in curvature appears to indicate a fluctuation in flowpath behavior for different water levels in these areas. At point A the July 2000 (low) water level appears to indicate that flow is dispersed to the southwest and southeast adjacent to and northwest of this point. However, the December 2004 (high) water level at point A appears to indicate that flow is concentrated along this general trend line. The opposite is true for

point B, where the July data indicate a concentration of flow from this point north and northwest, whereas the December data indicate that flow appears to be dispersed to the southwest and southeast along the same trend line. Although further study will reveal more information regarding this behavior, it appears that different flowpaths may be active within the same area as a result of changes in aquifer levels.

Another aspect of the two-system maps is the inclusion of fault data in the map. Faults as mapped by the USGS (1994, 1995, 1997, 2000, 2003) and the Bureau of Economic Geology have been combined and included in the two-system maps. Incorporating fault data for these maps enables the user of the data sets to ascertain potential relationships between structure and groundwater gradients.

The SWLP events plotted as two-system maps were selected on the basis of the criteria outlined in Table 2, below.

Table 2. Summary of Two-System Potentiometric Surface Maps

SWLP Map Date	Groundwater Elevation at Bexar County Index Well J-17	Groundwater Elevation at Uvalde County Index Well J-27	Criteria for Selection
July 17 through July 25, 2000	645' msl ¹	869' msl ²	SWLP lowest groundwater level event.
October 29 through November 2, 2001	675' msl	875' msl	SWLP event with water level closest to the mean (SWLP) groundwater level of 677' msl.
November 12 through November 19, 2002	697' msl	882' msl	SWLP initial maximum, plotted prior to new maximum value reached in December 2004.
July 19 through July 30, 2004	687' msl	882' msl	SWLP event for which additional data were available near the Hays County groundwater divide and Medina County recharge zone. Plotted as a two-system map to better define the potentiometric surface in these areas.
December 6 through December 13, 2004	701' msl ³	884' msl ⁴	SWLP maximum groundwater level event.

Notes: msl = mean sea level; readings are in feet above mean sea level

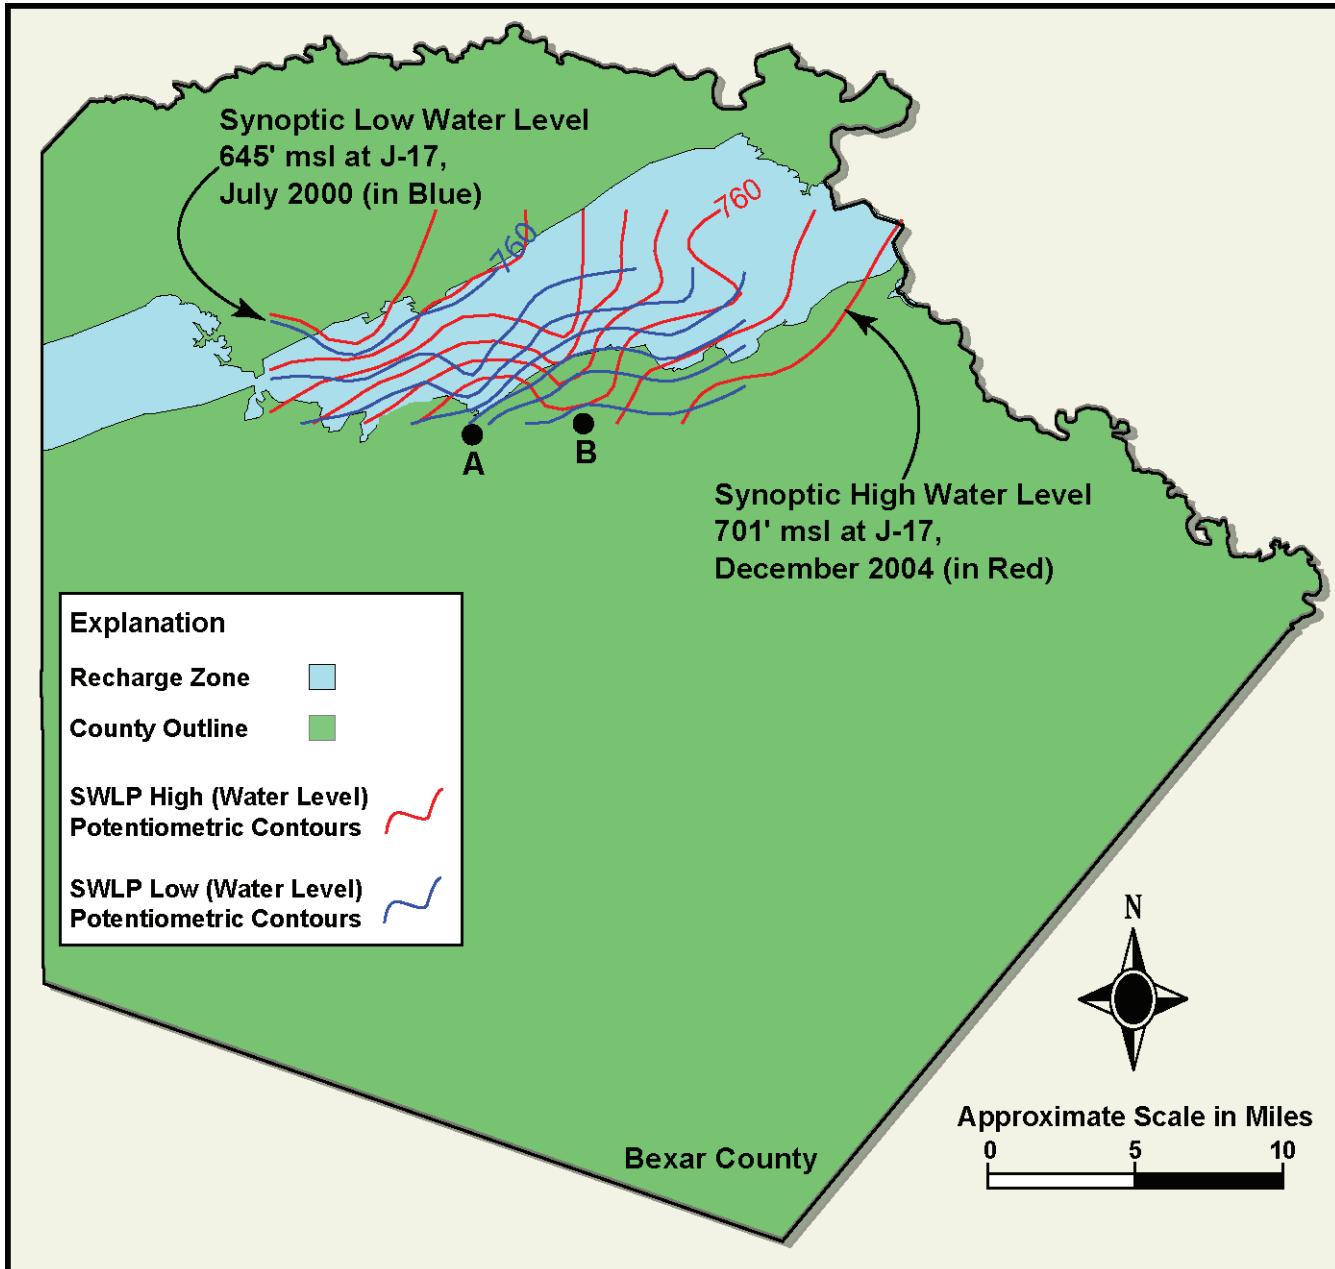

¹= SWLP low value for index well J-17

²= SWLP low value for index well J-27

³= SWLP high value for index well J-17

⁴= SWLP high value for index well J27

Figure 5. Comparison of High and Low Synoptic Water Levels in Bexar County Recharge Zone

Single-System Maps

Eleven of the SWLP events were modeled as single-system maps, in which all data points were treated as a single system, making no distinction between artesian or recharge zone. These maps do not exhibit the same variations or resolution between recharge and artesian zones as do the two-system maps. However, they are useful for displaying a general groundwater gradient for the aquifer, when modeled as a single homogeneous system. Local variations certainly exist within the groundwater surface across the area, but as previously discussed,

additional data points and/or different plotting methods are required in order for this level of resolution to be obtained.

The October 1999 and October 2000 maps have the same groundwater elevations at index well J-17 (662 feet msl); however, the index well J-27 groundwater elevations differ slightly (879 feet msl versus 869 feet msl at index well J-27). In addition, some variation in lines of equipotential may occur because of variations in the data set, such as inclusion or exclusion of different wells between events.

Table 3. Summary of Single-System Potentiometric Surface Maps

SWLP Map Date	Groundwater Elevation at Bexar County Index Well J-17	Groundwater Elevation at Uvalde County Index Well J-27	Comments
July 19 through July 23, 1999	674' msl	881' msl	(Index well J-17 within one foot of two-system map for 10/2001)
October 25 through October 29, 1999	662' msl	879' msl	
January 23 through February 3, 2000	664' msl	878' msl	
October 30 through November 3, 2000	662' msl	869' msl	(Index well J-27 = same level for July 2000, two-system map)
February 9 through February 16, 2001	680' msl	875' msl	(Index well J-27 = same level for October 2001, two-system map)
July 23 through July 27, 2001	658' msl	873' msl	
January 28 through February 4, 2002	682' msl	878' msl	
July 23 through August 2, 2002	689' msl	878' msl	
February 3 through February 7, 2003	697' msl	882' msl	(Index well J-17 = same level for November 2002, two-system map)
July 21 through July 25, 2003	684' msl	879' msl	
October 24 through October 31, 2003	683' msl	880' msl	

Notes: msl = mean sea level; readings are in feet above mean sea level

Differences between the two map types are summarized in Figures 6 and 7. Figure 6 provides an example of a two-system map for the December 2004 SWLP event. Figure 7 provides an example of a single-system map for the July 1999 SWLP event. As can be seen in the maps, the general shape

of the water surface (as represented by the contour lines) is similar for both maps for the artesian part of the aquifer. However, significant differences can be noted for the recharge zone area of the two-system map in Figure 6.

Figure 6. Two-System Map for December 2004

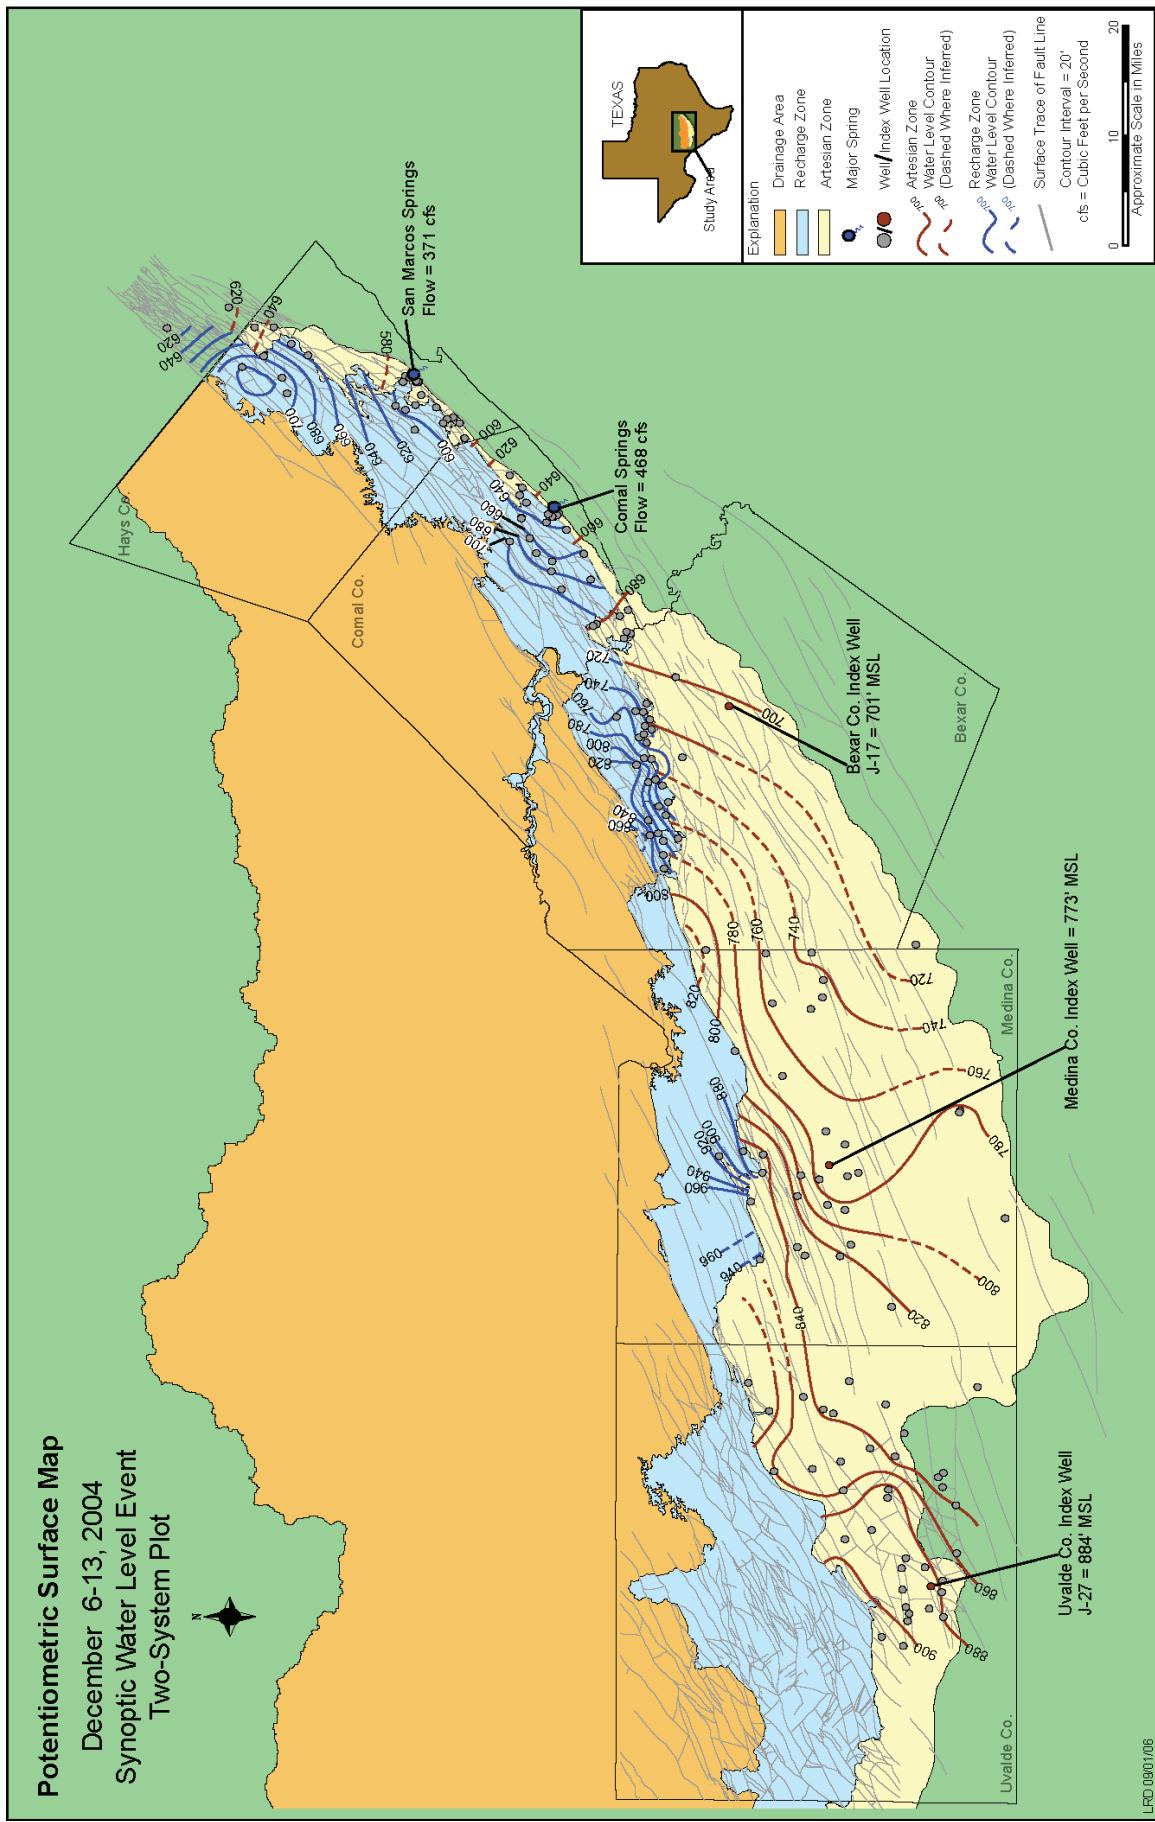

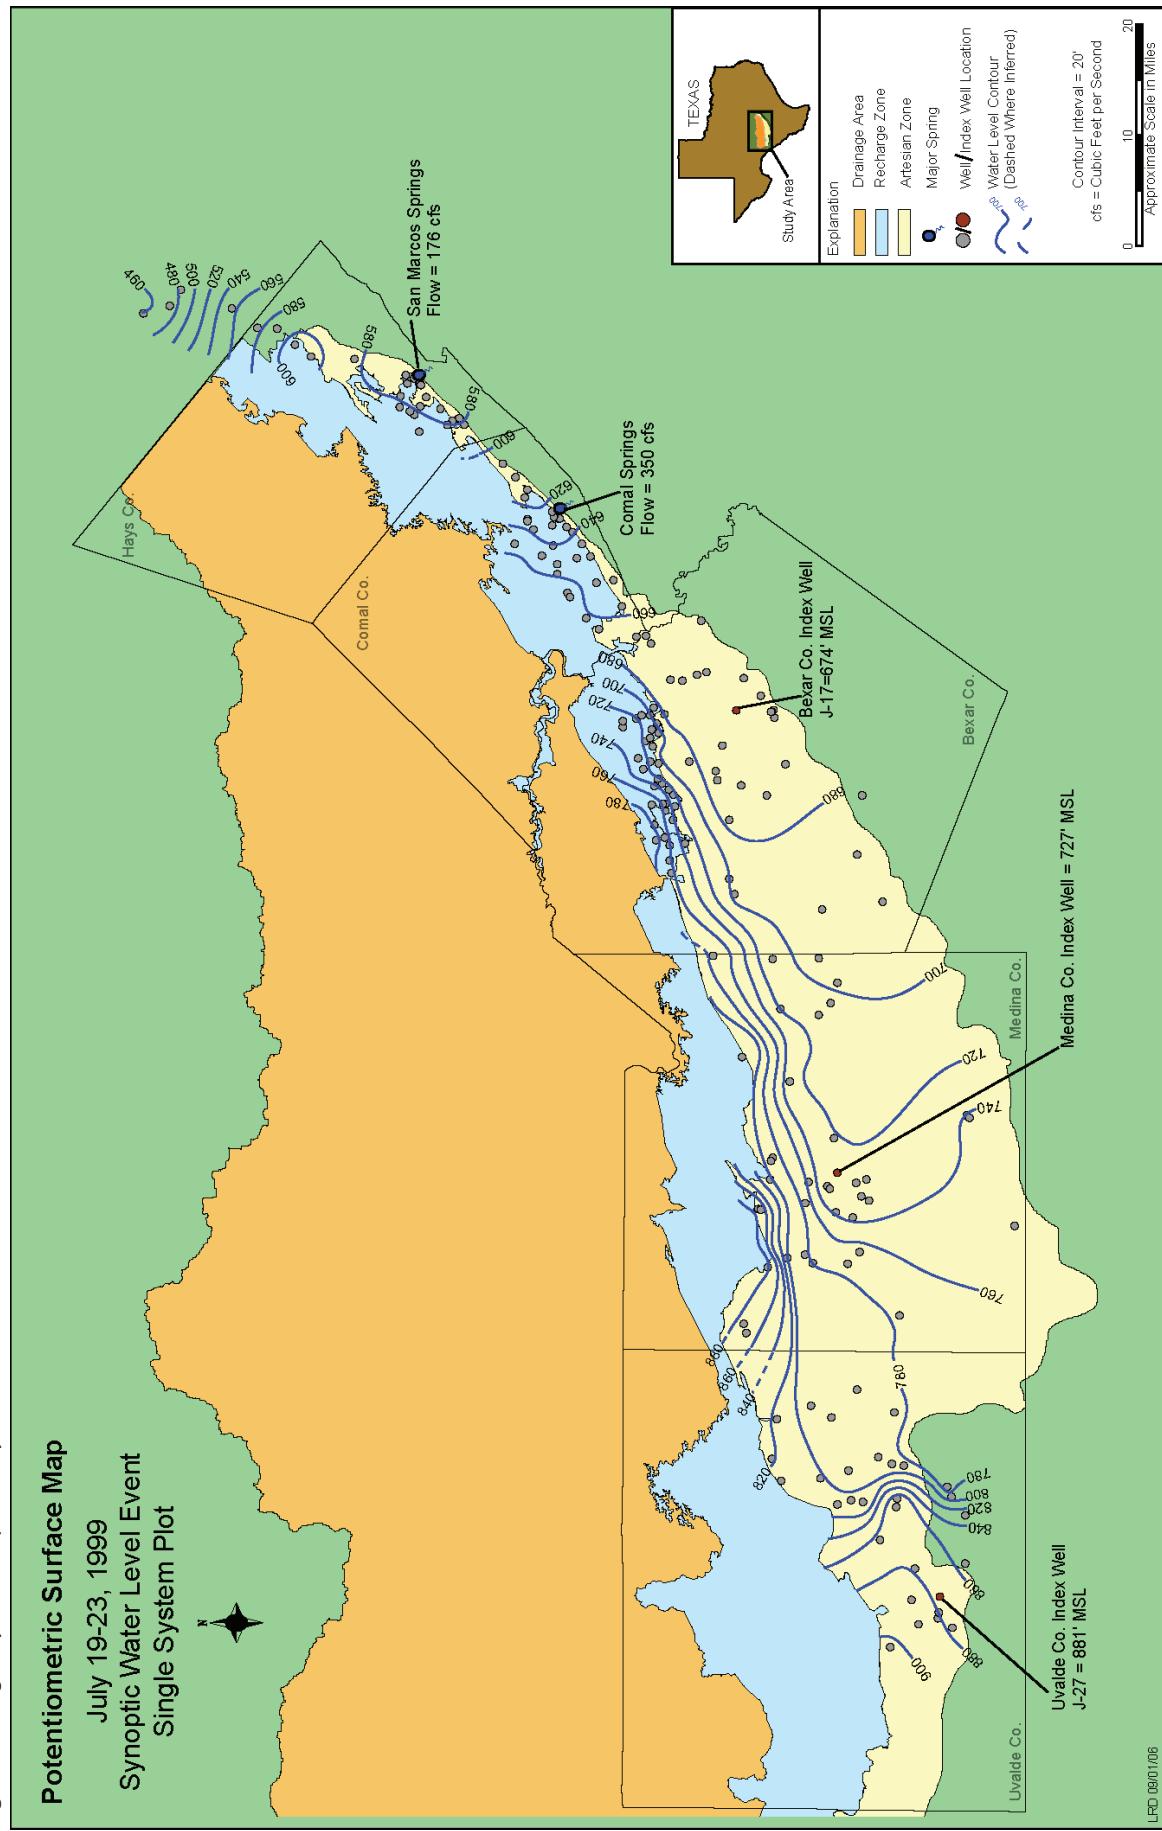

Figure 7. Single-System Map for July 1999

Recommendations and Conclusions

The SWLP provides excellent data regarding groundwater levels and potential flowpaths within the Edwards Aquifer. Compilation and reporting of these data by the Authority will help to further the overall understanding of groundwater behavior within the system, as well as aid in the recognition of areas where further study is required. This report is not intended as a comprehensive study of the data sets, or of the hydrogeologic factors affecting groundwater behavior in the aquifer. Rather, it is a forum for providing interested parties access to the data from a single source. The report is also aimed at satisfying the original intent of the TAG, which is to obtain water level data for model calibration efforts and develop potentiometric surface maps for the region. Furthermore, the report provides a set of maps that model the data in two ways: two-system models for five of the events and single-system models for the remaining 11 events. Interested parties may wish to plot or model the data differently in order to obtain enhanced detail in particular areas.

Areas that exhibit potentiometric or water surface variations worthy of further study include the Knippa Gap, Comal and San Marcos springs, northern Hays County, and the recharge zone in Bexar and Medina counties. It is likely that additional variations may be seen as data density is increased through efforts of the focused synoptic program. Many areas would benefit from focused synoptic events and/or inclusion of additional wells in the data collection process, including the recharge zone in Uvalde, Medina, Comal, and Hays counties, as well as parts of the artesian zone throughout the region. In addition, performing focused events that investigate the Trinity Aquifer system simultaneously with the Edwards Aquifer Recharge Zone may aid in our understanding of the interactions between these two aquifers.

In conclusion, the synoptic data reported herein effectively summarize the shape of the water surface in the Edwards Aquifer on a regional scale for a range of aquifer water levels. This summary was

accomplished by collection, validation, and analysis of the 16 synoptic data sets included herein. The study also indicates that localized variations exist in the aquifer's flow regime, with the most prominent variations apparently occurring between recharge and artesian zones. The study has also confirmed the need to collect focused synoptic data in order for more insight to be gained with regard to flowpaths within the aquifer. The variations detected in the recharge zone of Bexar County confirm the efficacy of additional data points (see Figure 5).

In the future, combining the results of this and future synoptic work with the results of other flowpath studies should also be beneficial to the science base for the Edwards Aquifer. For example, tracer study locations may be selected on the basis of synoptic results or combined with synoptic results to better define our understanding of the system.

This study has also effectively identified areas in need of more detailed investigation, such as the Knippa Gap, Cibolo Creek area, Hays County groundwater divide, and the interface between the Trinity and Edwards aquifers, as well as the recharge and artesian zone boundary within the Edwards Aquifer.

The Authority will continue to collect regional synoptic data annually with the help of cooperators. Without the cooperative effort of these entities, it would be impossible to collect the quantity or quality of data across the entire region that have been obtained in the past. In future years, the regionwide data collection event will be limited to one or two annual events, if water levels do not exceed or fall below previously recorded levels. However, the program will be modified to include a series of focused synoptic events over time, as well as an annual regionwide event. Collection of regional and focused synoptic data will help to improve the general understanding of the system and the flowpaths that exist within it.

Acknowledgments

The Edwards Aquifer Authority extends its appreciation to the agencies (Federal, State, and local) and well owners who have participated in the Synoptic Water Level Program by collecting data or allowing access to wells, land, and/or records. Furthermore, the Authority extends its gratitude to the San Antonio Water System (SAWS), United States Geological Survey (USGS)—Water

Resources Division—San Antonio Subdistrict, Barton Springs/Edwards Aquifer Conservation District (BSEACD), Texas Water Development Board (TWDB), and the Edwards Aquifer Research and Data Center (EARDC) for their efforts in measuring and compiling water levels from Edwards Aquifer wells.

Appendix D

Texas Water Development Board Well Numbering System

Wells used in this project are identified mainly by the Texas Water Development Board (TWDB) well-numbering system, which was developed by TWDB in a comprehensive *Ground-Water Data Dictionary* for use throughout Texas (Figure D.1) (Nordstrom and Quincy, 1999). The well-numbering system was established to facilitate well locations and avoid duplication of well numbers. Under this system, the state of Texas is divided into a grid of 1° quadrangles formed by degrees of latitude and longitude, and each quadrangle was given a two-digit number from 01 through 89. These are the first two digits of the well number.

Each 1° quadrangle is divided into 7½-minute quadrangles (similar to those on the 1:24,000 topographic quadrangle sheets), and each 7½-minute quadrangle is assigned another two-digit number from 01 through 64. These are the third and fourth digits of the well-identification number. Each 7½-minute quadrangle is divided into 2½-minute quadrangles numbered 1 through 9 for the fifth digit of the well number. As each well within

the 2½-minute quadrangle is inventoried, a number from 01 to 99 is appended to the one-digit 2½-minute quadrangle for the last three digits of the well number (Groschen and Buszka, 1997). Each well record stored in the TWDB Ground Water Data System is identified by this unique, seven-digit number. The system allows for the numbering of as many as 99 wells in each 2½-minute quadrangle. An eighth space is provided for future expansion of the numbering system and will allow numbering of as many as 999 wells in each 2½-minute quadrangle (Nordstrom and Quincy, 1999).

In addition, a pseudo-identification number was applied to wells not registered or identified by the TWDB system. The previously mentioned process was applied to nonregistered wells. The only exception was that a two-letter code, from AA through ZZ, was appended to the one-digit 2½-minute quadrangle number to complete the last three digits of the well number.
